TABLE OF CONTENTS

EXECUTIVE SUMMARY	<u>PAGE NO.</u>
ES.1 Introduction.....	ES-1
ES.2 Collection System	ES-1
ES.3 Single-Event Model	ES-2
ES.4 Continuous Simulation Model	ES-4
ES.5 Summary	ES-5
 CHAPTER 1 INTRODUCTION	
1.1 Purpose.....	1-1
1.2 Objectives	1-1
1.3 Goals	1-2
 CHAPTER 2 DESCRIPTION OF THE LAKEWOOD SEWER SYSTEM	
2.1 Introduction.....	2-1
2.2 Description of the Sewer System.....	2-2
2.3 Types of Sewer Trench Construction	2-6
2.4 Summary of Previous Sewer System Mapping/Modeling.....	2-8
2.5 Current Sewer System Mapping/Modeling	2-11
2.6 Permitted Overflows	2-12
2.7 Untreated Sewage Release Points.....	2-13
2.8 Sewer Connection Configurations	2-15
2.8.1 Type1: Combined to Over/Under Junction Manhole.....	2-15
2.8.2 Type 2: Side Flow Weir- Shelf	2-16
2.8.3 Type 3: Side Flow Weir - Invert	2-16
2.8.4 Type 4: Side Flow Weir – Single Pipe System.....	2-17
2.8.5 Type 5: Bottom Flow Orifice.....	2-17
2.8.6 Type 6: Direct Pipe Connection.....	2-17
2.8.7 Type 7: Leaping Wier	2-17
2.8.8 Type 8: Cross Channels	2-17
2.8.9 Type 9: Relief Ports	2-17
2.9 Illicit Connections	2-24
2.10 Cross Connections	2-25
 CHAPTER 3 COMPUTER MODEL CONSTRUCTION	
3.1 Software	3-1
3.1.1 SWMM Applications	3-1
3.1.2 SWMM Advantages.....	3-2
3.2 Purpose of the Model.....	3-2
3.3 Level of Detail	3-3
3.3.1 Skeletal Planning Model	3-3
3.3.2 Drainage Area Planning Model	3-4

3.3.3	Detailed Drainage Model.....	3-4
3.4	Complexity.....	3-4
3.4.1	Interaction between Systems.....	3-5
3.4.2	Special Hydraulic Structures.....	3-5
3.4.3	Northeast Ohio Regional Sewer District Sewers	3-6

EXECUTIVE SUMMARY

ES.1 INTRODUCTION

The City of Lakewood (City) was issued a National Pollutant Discharge Elimination System (NPDES) Permit by the Ohio Environmental Protection Agency (OEPA) regarding discharges to the waters of the State of Ohio from the City's Wastewater Treatment Plant (WWTP). The City is negotiating with the United States Environmental Protection Agency (USEPA) to develop an Integrated Wet-Weather Improvements Plan (IWWIP) to address the nine combined sewer overflows (CSOs) within the City's collection system network.

To effectively develop an IWWIP that satisfies the requirements set forth by the Clean Water Act (CWA) and does not exceed the financial capabilities of the City, the City initiated a collection system modeling project to understand the complex system interactions. The primary objective of the Lakewood modeling project is to develop an updated computer model of the current sanitary sewer system for the City. The model is the primary tool used to study and evaluate the hydrologic and hydraulic performance of the City's sewer collection system and to explore improvement alternatives.

ES.2 COLLECTION SYSTEM

Most of the City's sewers follow the street layout and generally flow from the south to the north to the interceptor sewer that closely follows the location of Edgewater Drive. Once entering the interceptor sewer, the flow moves from east to west before turning south to the wastewater treatment plant (WWTP), located on the Rocky River at the southern end of West Clifton Boulevard.

The City's sewer collection system contains approximately 875,000 total linear feet of sewers (393,500 linear feet of sanitary sewers, 348,000 linear feet of storm sewers, and 133,500 linear feet of combined sewers) serving the nearly 52,000 City residents. Besides serving all of Lakewood, the Lakewood WWTP treats flow from 106 homes in the City of Rocky River.

Almost all of the sanitary sewers in the City were constructed in an "over/under" (O/U) configuration where the storm was constructed directly above the sanitary sewer. There are a few isolated streets with separate trench sanitary sewers and at least two streets with O/U sewers where the sanitary sewer is above the storm sewer.

The City of Lakewood has nine permitted combined sewer overflows. Three (3) permitted overflows discharge combined storm and wastewater to the Rocky River at the southwestern edge of the City's collection system. Six (6) permitted overflows discharge

to Lake Erie at the northern limits of the City's collection system. **Table ES.1** is a list of these structures and their locations.

Table ES.1: City of Lakewood Permitted Combined Sewer Overflows

CSO	Location	Receiving Water
002	W. Clifton	Lake Erie
052	Madison at Riverside	Rocky River
053	Valley Parkway	Rocky River
054	Detroit at Scenic	Rocky River
055	Edgewater at Kenneth	Lake Erie
056	Edgewater at Rosalie	Lake Erie
057	Lakewood Park	Lake Erie
058	Edgewater at Roy	Lake Erie
059	Gold Coast	Lake Erie

ES.3 SINGLE-EVENT MODEL

The SWMM model is a powerful tool for system analysis. The model results can provide insight to complicated hydraulics that may otherwise not be understood and identify potentially unknown problem areas in the system.

Before any precipitation events can be simulated in the model, a dry-weather flow (DWF) analysis must be executed. The purpose of DWF analysis is to characterize the sewer system's behavior when it is not under the influence of precipitation. The analysis of dry-weather is the basis for all other model calibration efforts and applications. DWF calibration for the Lakewood model was evaluated against Wastewater Planning and Users Group (WaPUG) calibration parameters. The DWF calibration met the WaPUG criteria for each meter. **Figure ES.1** is an example of the DWF calibration results. The graph shows the field measured data as a heavy black curve (M052 (obs)). The diurnal pattern is clearly evident in the observed data. The model generated flows are shown as a thin red curve (002-243_U and M052) on top of the observed data. Dry-weather flow calibration is discussed in detail in Chapter 5 of this report.

Figure ES.1: Example DWF Calibration Results

The general purpose of wet-weather flow (WWF) analysis is to characterize the sewer system's response under the influence of precipitation. The USEPA's Sanitary Sewer Overflow Analysis and Planning (SSOAP) Toolbox is the primary tool used to classify the WWF response. WWF parameters were input in the SWMM model from the information obtained from SSOAP. The WWF calibration was generally good. Several meters did not record quality data making WWF calibration extremely difficult. Meters with poor data were not used for calibration. **Figure ES.2** is an example of the single-event WWF calibration results. The graph shows the field measured data as a black curve (M015 Obs). The rainfall dependent response is clearly evident in the observed data. The model generated flows are shown as a red curve (055C672_055C008) on top of the observed data. Wet-weather flow calibration is discussed in detail in Chapter 6 of this report.

Figure ES.2: Example Single-Event WWF Calibration Results

ES.4 CONTINUOUS SIMULATION MODEL

The general purpose of continuous simulation is to characterize the sewer system's response to precipitation and recovery before subsequent precipitation events. The continuous simulation of the Lakewood system model is discussed in detail in Chapter 8 of this report.

The first continuous simulation model developed was used to simulate the flow monitoring period. After the continuous model was calibrated to the flow monitoring period, the typical year precipitation record was simulated in the calibrated model to determine the number of overflow activations and volume discharged during a typical precipitation conditions. The typical year modeled CSO activation results are summarized in **Figure ES.3**. The typical year model results show CSO-055 as the most active CSO and January as the most active month for CSO-055 activations. The configuration of CSO-055 is such that the water depth in the 30-inch sewer only needs to exceed seven inches to report as an activation. The continuous simulation model was calibrated to the available months' data for all meters and CSOs. Since January was not a metered month, the parameters were estimated. Modeled CSO-055 could be reporting a high number of activations and the other CSOs could be reporting low numbers of activations. Long-term metering and calibrating to the meter data would provide more confidence in the dormant season calibration.

Figure ES.3: Modeled CSO Activation Monthly Summary: Typical Year

ES.5 SUMMARY

The most comprehensive collection system effort ever undertaken in the City of Lakewood was completed as part of this project. Field investigations revealed many unknowns about the City's sanitary, storm, and combined sewer networks. The field information was used to help build, calibrate, and analyze the SWMM model used to evaluate the performance of the sewer system.

Dry-weather flow calibration was the first step completed for model calibration. After DWF calibration, the model was calibrated for isolated, single, precipitation events. When the single-event calibration was complete, long-term continuous calibration and simulation was initiated. Using the calibrated continuous simulation model, a typical year precipitation record was simulated in the model to establish a baseline for the City's future IWWIP capital improvements. The results of the typical year model are summarized in **Table ES.2**.

Table ES.2: Modeled Typical Year CSO Frequency and Volume Summary¹

Overflow	Modeled Node	Conduit	Frequency (#/yr)	Volume (MG)
002	CSO002	002C002_CS0002	12	3.16
052	052T004	052S005_052T004	0	0.00

²CSO-056 is reported as one outfall, but is physically two pipes

CHAPTER 1 - INTRODUCTION

1.1 PURPOSE

The City of Lakewood (City) was issued a National Pollutant Discharge Elimination System (NPDES) Permit by the Ohio Environmental Protection Agency (OEPA) regarding discharges to the waters of the State of Ohio from the City's Wastewater Treatment Plant (WWTP). The City is negotiating with the United States Environmental Protection Agency (USEPA) to develop an integrated wet-weather control plan (IWWIP) to address the nine combined sewer overflows (CSOs) within the City's collection system network.

To effectively develop a IWWIP that satisfies the requirements set forth by the Clean Water Act (CWA) and does not exceed the financial capabilities of the City, the City initiated a collection system modeling project to understand the complex system interactions. Previous sewer studies did not adequately document the cross connections between the sanitary and storm sewer systems at over/under (O/U) sewers, locations where combined sewers flow into separate sewers, and illicit private connections.

The purpose of this study is to build, calibrate, and analyze a comprehensive sewer collection system model to help develop the goals of the IWWIP. The goals of the IWWIP are to:

- Bring all sewage overflow discharge points into compliance with the technology and water quality based requirements of the CWA and Ohio Revised Code Section 6111
- Minimize water quality and human health impacts
- Minimize the discharge of pollutants

1.2 OBJECTIVES

The primary objective of the Lakewood modeling project is to develop an updated computer model of the current sanitary sewer system for the City. The model is the primary tool used to study and evaluate the hydrologic and hydraulic performance of the City's sewer collection system and to explore improvement alternatives. The City established the following requirements and objectives for the model to meet the project goals:

- The model engine will be the USEPA Stormwater Management Model (SWMM) 5.0 hydrologic and hydraulic model
- The new model will be developed using existing sewer maps and collecting field data
- All City-owned sanitary sewers eight-inches in diameter and greater will be modeled in SWMM

- The model will be calibrated and verified for both dry- and wet-weather flows using data supplied from the City's flow monitoring network placed in 2011
- The model will be used to predict the frequency and volume of discharges at the outfalls to the environment for a typical year simulation
- The model will be used to provide the basis for designing improvement alternatives to eliminate sanitary sewer overflows (SSOs) and limit CSOs to an acceptable level as determined by the OEPA

1.3 GOALS

The sewer system model developed as part of the City's effort to control overflows stems from the need to understand how the sewer system functions. Unless a knowledge base is developed on the complex hydraulics inherent in the Lakewood sewer system, any plan to limit or eliminate overflows is highly likely to be ineffective and could potentially result in the City investing in projects that have little or no impact on overflow control.

The City embarked on developing a sewer system model using the USEPA SWMM software. To support development of the model, the City decided not to rely on previous mapping and modeling data since there was no way to verify the information was accurate or whether the information was obtained from a reliable source. A cursory review of previous mapping/modeling revealed that overflows located at the upper reaches of the sewer system were not incorporated into the model, and other overflows were simply overlooked by previous studies.

In conjunction with developing the SWMM model, the City dedicated a sewer crew to open manholes and trace majority of the sanitary sewer system within the City. Since many of the sewers are of the O/U configuration, this would also result in tracing of much of the City's storm sewer system. As the system was investigated, new maps of the sewer system were created representing sanitary sewers, combined sewers, storm sewers, and interceptor sewers. Also, sewers owned by the Northeast Ohio Regional Sewer District (NEORS) were differentiated.

The goals accomplished during the course of this project include:

1. Identify system outfalls, cross connections, and other locations of potential CSOs
2. Update sewer mapping
3. Build, calibrate, and analyze a comprehensive system model
4. Establish a baseline scenario for evaluating future system improvements using the typical year precipitation

CHAPTER 2 - DESCRIPTION OF THE LAKEWOOD SEWER SYSTEM

2.1 INTRODUCTION

The City of Lakewood is located in the State of Ohio on the shores of Lake Erie, just west of the City of Cleveland. Lakewood shares a border with the City of Cleveland on the east and south, the City of Rocky River on the west, and Lake Erie on the north. The Rocky River forms much of the western border between Lakewood and the City of Rocky River. **Figure 2.1** shows the location of the City of Lakewood.

The City of Lakewood (the City) is the third largest city (by population) in Cuyahoga County, out-ranked only by the City of Cleveland and the City of Parma. While the City is third in population, the 5.5 square mile City of Lakewood ranks first in population density in the entire State of Ohio. As home to approximately 52,000 residents, the population density of Lakewood rivals that of much larger cities such as Washington D.C.

The land surface in the City slopes uniformly northward toward Lake Erie except for a small portion of the City contiguous to the Rocky River which slopes toward the river. Roughly 66 percent of the City's storm sewer system discharges to Lake Erie with the balance discharging to the Rocky River. The City is located on a bluff that is 50 to 60 feet above Lake Erie and the Rocky River. There are no public beaches within the City except for a small private beach at the mouth of the Rocky River.

Figure 2.1: Lakewood, Ohio

2.2 DESCRIPTION OF THE SEWER SYSTEM

Most of the City's sewers follow the street layout and generally flow from the south to the north to the interceptor sewer that closely follows the location of Edgewater Drive. Once entering the interceptor sewer, the flow moves from east to west before turning south to the wastewater treatment plant (WWTP), located on the Rocky River at the southern end of West Clifton Boulevard.

The City's sewer collection system contains approximately 875,000 total linear feet of sewers (393,500 linear feet of sanitary sewers, 348,000 linear feet of storm sewers, and 133,500 linear feet of combined sewers) serving the nearly 52,000 City residents. Besides serving all of Lakewood, the Lakewood WWTP treats flow from 106 homes in the City of Rocky River. There are three small pump stations in the Lakewood sewer system, one of which is owned and operated by the Cleveland Metroparks.

Sewer construction began in the City around 1900. By 1930, approximately 80 percent of the sewers in the City had been constructed. A surrogate for the age of the sewer is the age of the buildings in the City. It is reasonable to assume that when the building was constructed, sewer service was provided. **Figure 2.2** shows the parcel age of the City by decade.

Almost all of the sanitary sewers in the City were constructed in an "over/under" (O/U) configuration where the storm was constructed directly above the sanitary sewer. There are a few isolated streets with separate trench sanitary sewers and at least two streets with O/U sewers where the sanitary sewer is above the storm sewer. The eastern 25 percent of the City is primarily combined sewers, although there are combined sewers on isolated streets in the western portion of the system. **Figure 2.3** shows the location of the City's sewers, color-coded by the type of sewer.

Records from the early 1900s are incomplete; however, from the information available, it is thought that the sanitary and combined collection systems are vitrified clay pipe (VCP) with brick and mortar manholes. Larger trunk sewers in the City adhere to the City of Cleveland's standard egg-shaped cross sections and most are constructed of brick with integral brick manholes. Also scattered throughout the City are larger diameter storm and sanitary sewers constructed of segmented loose laid tile pieces which depend on compressive soil forces to maintain their integrity. These sewers are found in both circular and egg-shaped cross sections. **Figure 2.4** shows the location of the City's sewers, color-coded by the shape of the sewer.

The City's main interceptor (constructed in phases over a 20-year period starting in the 1920s) is egg-shaped and constructed of segmented tiles. Most large sewers constructed after 1950 were constructed using concrete.

\\mtr-fs1\MTR-VOL1\2011\1101601\REPORTS\Ch-2\Figure 2-03 Sewer Type.mxd

2.3 TYPES OF SEWER TRENCH CONSTRUCTION

Any discussion of the Lakewood sewer system requires knowledge of the different types of sewer construction existing in the planning area.

The City of Lakewood sewer system has a substantial quantity of O/U sewers with the storm sewer directly above the sanitary and only one manhole to access both pipes. **Figure 2.5** illustrates the typical configuration of the O/U sewers. An invert plate in the “over” sewer allows access to the “under” sewer. O/U sewers were built predominantly during the 1920s and 30s although invert plate sewers were installed until the 1950s. This type of sewer is not known to exist anywhere else in the country other than in northeast Ohio.

INVERT PLATE SEWER CONSTRUCTION

Figure 2.5: Sketch of Over/Under Sewer Configuration

In O/U manholes, a trough shaped plate is laid across the storm sewer invert from the upstream conduit to the downstream conduit to convey storm water. The invert plate is grouted into place so storm water cannot enter the sanitary sewer below. In order to

access the sanitary sewer, the invert plate has to be physically pried open, breaking all the concrete grout. Maintenance crews leaving the manhole must re-grout the invert plate or it becomes a large inflow source during subsequent precipitation events.

During construction of the sanitary sewer (generally eight-inches to 12-inches in diameter) two-foot sections of VCP were laid on a bed of granular sand. Then the trench was backfilled with more granular sand to a depth of approximately six-inches above the crown of the sanitary sewer. The storm sewer was laid directly above the sanitary on that bedding. Backfilling with granular material continued to the springline of the storm sewer, (also generally built with two-foot VCP sections), and finally the trench was filled in with premium (granular) backfill. Cement joints were used during construction of both sewers. The O/U configuration of the sewer collection systems leaves the “under” sewer extremely susceptible to infiltration and inflow (I/I). Whatever joint sealing compound was originally used has deteriorated, so today, storm water can leak out of joints in the storm sewer, through the permeable backfill, and infiltrate the sanitary sewer joints.

Common trench sewers with separate manholes make up a very small portion of the City’s collection system. **Figure 2.6** illustrates the configuration of common trench sewers. Common trench sewers are laid in the same trench, but not directly over one another. The sanitary sewer was laid at the bottom of the trench and backfilled with the same type of porous granular sand used in O/U sewer construction. The storm sewer was laid on a bench above and partially off to the side of the sanitary sewer, and the trench was further backfilled with granular material to the springline of the storm sewer. From there, backfilling continued to street level using premium backfill. Typical joint materials used in construction of common trench sewers in the 1920s, 30s, and 40s were jute and mortar or asphalt. Bituminous slip seal joints were used in the 1950s, and since the 1960s, premium joint pipes have been used (e.g. “water tight” rubber gaskets).

In general, the dual manholes in common trench sewers are built as one box structure with two chimneys, one for the sanitary, and one for the storm sewer. The side of the storm sewer usually bulges through the wall of the sanitary chimney.

Private house laterals and private business laterals typically comprise approximately half (or more) of the linear footage of sewers in the City’s sewer system. Over 90 percent of the private laterals were constructed in common trenches with whatever joint material that was in use at the time of construction. In some of the older areas of the City, over 90 percent of private laterals contribute storm water I/I to the sanitary sewer system. Most of the private lateral infiltration problems are indirect connections (e.g. disconnected downspouts, yard infiltration) rather than direct storm water connections (e.g. driveway drains, catch basins) to the sanitary sewer.

COMMON TRENCH SEWER

Figure 2.6: Sketch of Common Trench Sewer Configuration

2.4 SUMMARY OF PREVIOUS SEWER SYSTEM MAPPING/MODELING

Historically, Lakewood's sewer system maps have been two-dimensional schematic maps. These maps, while drawn to scale, were tied to local coordinates (e.g. elevation above mean Lake Erie level) not global coordinates (e.g. elevation above mean sea level or US NAV29 datum). The earliest sewer system maps that the City has in their files are dated 1917 and were originally drawn at a scale of 1 inch = 200 feet (**Figure 2.7 and Figure 2.8**). O/U sewer construction was shown as a single line with two size notations; one size for the storm sewer and the other size for the sanitary sewer. The numbers were shown one over the other with the storm sewer being the upper (and usually larger) number. Combined sewers were indicated by a single sewer size designation. Storm sewers, while shown, were generally indistinguishable from other sewers. The map was originally drawn in ink with updates added in pencil. Elevations at many manholes are indicated with top of casting and invert elevations referencing feet above lake level.

Figure 2.7

Figure 2.8

A new sewer system map and computer model was developed in 1975 by Watermation Incorporated of Saint Paul, Minnesota to support the City's Wastewater Facility Plan (also by Watermation), completed in 1978. The model was written in Fortran IV and run on an IBM 370 (or similar) size mainframe computer. The model was skeletal, incorporating only the interceptor, major trunk sewers, and regulators. Catchments representing large drainage areas (including collector and local sewers) were developed as inputs to the skeletal sewer system. The analysis was limited to modeling a single 10-year storm event.

Havens & Emerson Consultants of Cleveland, Ohio were retained to perform an *Inflow Identification Program* in 1984, a *Madison Avenue Drainage Study* in 1991, and a *CSO Operational and Maintenance Plan* in 1992. All of these studies were limited in scope and geographical area – none encompassed the entire sewer system although the 1992 study did advance the understanding of the CSO regulators along the Rocky River and Lake Erie shoreline.

In 2000, CDM (now CDM Smith) was retained to populate the City's GIS database for the sanitary sewer system tributary to the permitted CSO outfalls. CDM Smith inspected, sketched, and photographed approximately 638 manholes, which constitutes about 25 percent of the City's sanitary sewer system. The project was terminated when funding expired. While the individual manhole details obtained during this project are valuable, they lacked connectivity to each other and therefore do not enhance the understanding of how the sewer system functions. No system map updates were produced under this project.

The City retained Metcalf and Eddy (now AECOM) in 2003 to prepare a long term control plan (LTCP) for control of combined sewer overflows. A sewer system model was developed using DHI MOUSE 2003 software (a predecessor to DHI's Mike Urban software), a proprietary modeling platform that the City does not own. The model was limited to the interceptors, trunk sewers, and selected collector sewers using existing sewer information and record drawings. It was acknowledged in the model documentation that a significant number of regulators (e.g. overflows) were not identified and therefore were not included in the model. While the LTCP advanced a strategy to limit the number of overflows to less than four in a typical year, the lack of a fundamental understanding of the sewer system inhibited its effectiveness. No updates to the sewer system mapping were done as part of this project.

2.5 CURRENT SEWER SYSTEM MAPPING/MODELING

The sewer system model developed as part of the City's effort to control overflows stems from the need to understand how the sewer system functions. Unless a knowledge base is developed on the complex hydraulics inherent in the Lakewood sewer system, any plan to limit or eliminate overflows is highly likely to be ineffective and could potentially result in the City investing in projects that have little or no impact on overflow control. None

of the previous mapping updates nor models were developed using software that was readily available on the open market which the City could acquire at little or no cost. With these caveats, the City embarked on developing a sewer system model using the Storm Water Management Model (SWMM) software developed by the United States Environmental Protection Agency (USEPA). This software has been thoroughly tested and is widely accepted for storm sewer and sanitary sewer analysis and was written using the C software language. The current version is SWMM 5.1.005 and enhancements have been made to model sanitary sewers as well as storm systems including green infrastructure practices. Since the software is available free of charge from the USEPA and because it has become the modeling software of choice for a variety of sewer systems, this software was chosen for developing a comprehensive model of Lakewood's collection system.

To support development of the model, the City decided not to rely on previous mapping and modeling data since there was no way to verify the information was accurate or whether the information was obtained from an unreliable source. A cursory review of previous mapping/modeling revealed that overflows located at the upper reaches of the sewer system were not incorporated into the model, and other overflows were simply overlooked by previous studies.

Therefore, in conjunction with developing the SWMM model, the City dedicated a sewer crew to open manholes and trace all of the sanitary sewer system within the City. Since many of the sewers are of the O/U configuration, this would also result in tracing of much of the City's storm sewer system. As the system was investigated, new maps (in AutoCAD) of the sewer system were created using different line types representing sanitary sewers, combined sewers, storm sewers, and interceptor sewers. Also sewers owned by the Northeast Ohio Regional Sewer District (NEORS) were differentiated. To assist in the understanding of the interconnectivity, enlargements of key intersections and sewer junctions were developed and included on the new sewer system maps. Key manholes were identified with unique identifying numbers indexed to permitted CSO's in the City's NPDES permit. All outfalls to Lake Erie and the Rocky River identified in an outfall survey conducted in 2007 for the City by AECOM were cross referenced and identified on the maps (exceptions being four-inch and six-inch outfalls from private property).

The intensive field investigation of the sewer system identified an additional 51 locations where untreated sewage could migrate to pipes that ultimately discharge to the Rocky River or Lake Erie without treatment. These points had not been incorporated into previous models nor located and identified in previous sewer system maps.

2.6 PERMITTED OVERFLOWS

The City of Lakewood currently has nine permitted combined sewer overflows. **Figure 2.9** shows the locations of the permitted overflows. Three (3) permitted overflows

discharge combined storm and wastewater to the Rocky River at the southwestern edge of the City’s collection system. Six (6) permitted overflows discharge to Lake Erie at the northern limits of the City’s collection system. **Table 2.1** is a list of these structures and their locations.

Table 2.1: City of Lakewood Permitted Combined Sewer Overflows

2.7 UNTREATED SEWAGE RELEASE POINTS

The City has a variety of structures in the sewer collection network that were installed to prevent overloading of sewers that could result in basement flooding. These structures were most likely constructed on an “as-needed” basis as a result of property owner complaints or observed street flooding. Due to poor historic documentation and difficult site access, many of the untreated sewage release points were not well-known until the comprehensive effort of this study revealed the connectivity of the sewer system and identified these possible points of cross-connection. The structures were constructed to protect the health and safety of the users of the sewer system, or were installed to provide access for maintenance.

\\mtr-fs1\mtr-vol11\101601\REPORTS\Ch-2\Figure 2-09 Overflow Locations.mxd

Figure 2.9

2.8 SEWER CONNECTION CONFIGURATIONS

The configurations of the untreated sewerage release points spotted throughout the system are diverse and are described in Sections 2.8.1 through 2.8.8.

2.8.1 TYPE 1: COMBINED TO OVER/UNDER JUNCTION MANHOLE

A leaping weir manhole is typically located where a combined sewer connects to an O/U sewer configuration. **Figure 2.10** is a sketch of the leaping weir configuration. A single combined sewer pipe enters the manhole and two pipes exit the manhole; a lower pipe connected to the “under” sewer and an upper pipe connected to the “over” sewer. During dry-weather and minor rain events, the flow enters the lower pipe to the “under” sewer. During heavier rainfall events, flow continues to enter the “under” pipe until its capacity is exceeded. The hydraulic grade line (HGL) rises until combined flow enters the upper pipe which discharges to the “over” sewer. The “over” sewer is typically connected to an outfall at the river or lake and discharged without treatment.

The City’s SWMM model was constructed to model this configuration using two pipes exiting a node and connecting to the appropriate O/U sewer. SWMM will calculate the number of times this type the “over” pipe activates, the peak flow rate in a typical year, and the total volume.

Figure 2.10: Leaping Weir

2.8.2 TYPE 2: SIDE FLOW WEIR - SHELF

Figure 2.11 is a photograph of a typical side flow weir located in the upper part of a manhole on a brick shelf spanning the manhole. The apparent purpose was to provide access to the upper sewer which usually conveyed sanitary sewage. The weir height typically was at the crown of the upper sewer or higher. The lower sewer in the manholes is typically connected to an outfall at the river or lake and discharged without treatment. In SWMM, this configuration is modeled using a side weir equation.

Figure 2.11: Side Flow Weir - Shelf

2.8.3 TYPE 3: SIDE FLOW WEIR - INVERT

This type of side flow weir is located at the bottom of the manhole where two pipes enter the manhole side-by-side. One pipe is ultimately conveys flow to the WWTP while the other pipe is connected to an outfall to the river or lake. The apparent purpose was to provide access to both sewers in a single manhole. The weir height typically is lower than the crowns of the pipes. In SWMM, this configuration is modeled using a side weir equation. **Figure 2.12** is a photograph of this type of structure.

Figure 2.12: Side Flow Weir - Invert

2.8.4 TYPE 4: SIDE FLOW WEIR – SINGLE PIPE SYSTEM

This type of side flow weir is located at the bottom of the manhole where a single pipe enters the manhole. During low flow, sewage is directed and retained within the single pipe that enters and exits the manhole. During wet-weather, if the flow exceeds the capacity of the pipe, then flow crests the weir and is usually directed to an outfall at the lake. The weir height typically is lower than the crown of the pipe. In SWMM, this configuration is modeled using a side weir equation.

2.8.5 TYPE 5: BOTTOM FLOW ORIFICE

Similar to the leaping weir, an orifice in the bottom of a manhole allows dry-weather flow to drop through to a sewer below. Wet-weather causes the flow rate to exceed the capacity of the bottom orifice and flow is directed to a sewer which ultimately discharges untreated to the lake. Unlike the leaping weir configuration, there is no weir immediately downstream of the bottom flow orifice to create additional head on the orifice increasing the flow through the orifice. In SWMM, this configuration is modeled using an orifice equation.

2.8.6 TYPE 6: DIRECT PIPE CONNECTION

Existing, but less prevalent, in the Lakewood sewer system are direct pipe connections between manholes carrying sewage and sewers that discharge flow that is untreated to the river or lake. In SWMM, this configuration is modeled using a side opening orifice equation for short pipes or as a conduit link between nodes for longer pipes.

2.8.7 TYPE 7: LEAPING WEIR

Figure 2.10 is a sketch of a leaping weir. An orifice in the bottom of the manhole allows dry weather flow to drop through to a sewer below. Wet weather causes flow to jump over the orifice to a sewer beyond the orifice opening. The flow jumping over the orifice continues to a pipe network that ultimately connects to an outfall at the lake. In SWMM, this configuration is modeled as a bottom orifice.

2.8.8 TYPE 8: CROSS CHANNELS

This type is found typically where large diameter sewers that could potentially carry sewage and storm water cross the City's major interceptor. A shallow channel crosses perpendicularly at the invert of the large sewer. Low flow is captured by the shallow channel and directed to the interceptor. Larger flows continue to an outfall at the lake. In SWMM, this configuration is modeled as a leaping weir.

2.8.9 TYPE 9: RELIEF PORTS

Figure 2.13 shows an inadvertent connection between O//U sewers in manholes that were constructed during the 1930s as part of the Works Progress Administration (WPA) program. In these manholes, a 6-inch pipe extends from

the lower sewer to the shelf at the springline (or higher) of the upper sewer. The pipe was capped at the shelf with a hinged cedar flapper. These manholes also have invert plates in them. Apparently, the pipe was designed to relieve pressure in the lower sewer during surcharging and thereby preventing dislodging of the invert plate. However, over time, the cedar flappers and carbon steel hinges have rotted or corroded away, leaving a direct open connection between the two sewers. In SWMM, these ports are modeled as a side orifice.

Figure 2.13: Relief Port

Table 2.2 lists the identified overflows in the City during the flow monitoring period and the structure type described in Section 2.8.1 through Section 2.8.9.

Table 2.2: Potential Overflow Locations

Outfall	Manhole	Location	Description	Type of Overflow Structure
LEWS 1035	059-14	Thoreau Avenue at Clifton Blvd.	Combined sewer flow drops through offset invert plate to combined sewer on Clifton Blvd.; wet weather flow bypasses invert plate to storm sewer.	5
LEWS 1035	059-30	City Hall to Thoreau Avenue	Flow could overtop longitudinal weir in common MH.	3

RRES 1145	002-006	1564 Spring Garden	Relief port between sanitary and storm, appears to be blocked	9
RRES 1145	002-010	1669 Winton	Relief port between sanitary and storm, appears to be blocked	9
RRES 1145	002-258	Clifton Blvd. at West Clifton Blvd.	San. flow in common manhole can overtop weir into storm sewer.	3
RRES 1160	052-90	Olive Avenue at Hilliard Road	Underflow from combined sewer drops into sanitary sewer; overflow to storm sewer on Madison Avenue.	6

2.9 ILLICIT CONNECTIONS

Illicit connections are defined as "illegal and/or improper" connections of a sanitary sewer or sanitary lateral to a storm sewer **Table 2.3** is a list of illicit connections discovered through field investigations and review of record drawings.

Table 2.3: Illicit Connections

CSO Area	Manhole	Location	Description
002	002-200	Lake and Webb	002-200 receives sanitary from homes on Webb btw Clifton and Lake. 002-200 is connected to the 72" storm sewer on Webb going to Lake Erie
002	002-258	Clifton Blvd. and West Clifton Blvd.	Sanitary from MH 002-258 flows through a 12" Comb. to the 60" storm
002	002-207	Lake btw Kenneth and Webb	Low flows from 002-206 enter storm sewer in 002-207.
002C		Wayne and Crest Lane	All low flows on Crest Lane go into the storm sewer (storm is under) on Wayne Avenue.
002D	002-169	Clifton and Webb	12" combined from the north side of Clifton, east of Webb connects to 002-169. O/U on the north side of Clifton, west of Webb connects to 002-169. 002-169 connects to the 72" storm that outfalls into the Lake.
002E	002-216	Lake Avenue at Summit Avenue	Lake Ave. 30" comb. sewer from west appears to connect to storm sewer on Summit Avenue. Need to confirm if 1) Lake Avenue sewer is combined, 2) if it connects to storm sewer (blind) south of MH #216.
058	058-14	Merl Avenue btw Manor Park and Chase	Sanitary from the Winking Lizard is connected to the storm on Merl.
059A		13425 Detroit (Dentist Office)	Sanitary lateral connected to 48" storm. New sanitary lateral installed for future separation (Per Detroit Avenue Sewer Rehabilitation)

The illicit connections identified in **Table 2.3** will be added to the City's priority list for sewer improvements and repairs. Where sanitary sewers connect directly to the stormwater collection system, the sewer will be disconnected from the storm sewer system and connected to the sanitary sewer collection system.

2.10 CROSS CONNECTIONS

Cross connections are defined as improper connections of a storm sewer or storm sewer lateral to a sanitary sewer resulting in unnecessary storm water in the sanitary system. **Table 2.4** is a list of cross connections that have been identified within the City.

Table 2.4: Cross Connections

CSO Area	Manhole	Location	Description
002A	002-93	Sloan at West Clifton	CBs connected to sanitary
002D	002-193	Clifton Blvd. at Granger Avenue	Stormwater can overflow from the 27" storm sewer on the south side of Clifton Blvd. to the combined sewer on the north side of Clifton Blvd.
002G	HCT-3, HCT-4, HCT-14	Parkside	The outlet for the storm sewer on Parkside is blocked so the storm fill up until it overflows into the sanitary which is above the storm
052		Bayes Ave.	O/U sewers in center of street connect to combined sewer on south side of Bayes.
052		Brown Rd. at Bayes Ave.	O/U sewer on Brown connects to combined on Bayes.
052	115	Arden Avenue	MH is labeled sanitary, but has a CB tying into it.
052	052-152	Northland Ave. at Fischer Rd.	Separate storm sewer from Northland connects to combined on Fischer although a storm sewer is available on Fischer. Check NEORS D relief sewer drawings for this area. Similar situations may occur at Woodward/Fischer and Atkins/Fischer.
056	056-08	Lake between Belle and Cook	CB connected to sanitary
059A		14133 Detroit (McGorray Funeral Home)	Storm lateral connected to sanitary lateral. New storm lateral installed for future separation (Per Detroit Avenue Sewer Rehabilitation)
059A		14125 Detroit (Hixson Flowers)	Storm lateral connected to sanitary lateral. New storm lateral installed for future separation (Per Detroit Avenue Sewer Rehabilitation)
059A		14013 Detroit (Giant Eagle)	Parking lot and drains behind bldg are connected to sanitary lateral. (Per Detroit Avenue Sewer Rehabilitation)
059A		13521 Detroit (Private Home)	Storm lateral connected to sanitary lateral. New storm lateral installed for future separation (Per Detroit Avenue Sewer Rehabilitation)
059A		13443 Detroit (Brinkman Funeral Home)	Storm lateral connected to sanitary lateral. New storm lateral installed for future separation (Per Detroit Avenue Sewer Rehabilitation)
059A		13335 Detroit (Nicholson House)	Storm lateral connected to sanitary lateral. New storm lateral installed for future separation (Per Detroit Avenue Sewer Rehabilitation)
059B	Survey Manhole 852	Cliff and Nicholson	CB connected to sanitary

CHAPTER 3 – COMPUTER MODEL CONSTRUCTION

3.1 SOFTWARE

When the City of Lakewood (City) committed to developing a detailed model of its sewer collection system, it was desired to use a modeling platform that is publicly available, capable of modeling complex hydraulics, and affordable. The City chose the United States Environmental Protection Agency's (USEPA) Storm Water Management Model (SWMM) as the platform to create their system model.

SWMM is a dynamic simulation model used for single-event and long-term precipitation, runoff, and collection system modeling. It is one of the most common publicly available software programs used for analysis, design, and planning of stormwater collection systems, combined sewer systems, and sanitary sewer collection systems. SWMM is used to simulate catchment area hydrology and conveyance system hydraulics from primarily urban areas, although suburban and rural areas have been successfully modeled in SWMM as well.

The general operation of the model is relatively simple and intuitive. During a simulation, precipitation is simulated over hydrologic subcatchments and excess precipitation (that which exceeds the infiltration rate of a given subcatchment) becomes runoff. The runoff is computed by a non-linear reservoir routing equation and is then hydraulically routed through a collection system by applying the continuity equation coupled with the momentum equation or full St. Venant dynamic flow routing equation. During a simulation, SWMM performs the hydrologic and hydraulic calculations at regular time intervals and tracks the quantity and quality of runoff from each subcatchment, the flow rate, flow depth, and quality of water in each node and link.

3.1.1 SWMM APPLICATIONS

As a stormwater management tool, the SWMM model is typically applied to the designing and sizing drainage system components, sizing detention facilities, analyzing flood control, protecting water quality, mapping flood plain limits, and generating non-point source pollutant loadings for waste load allocation studies. SWMM is also a Federal Emergency Management Agency (FEMA) approved model for National Flood Insurance Program (NFIP) studies. Traditional sanitary sewer applications include evaluating the impact of inflow and infiltration (I/I) on sanitary sewer systems, analyzing sanitary sewer overflows (SSOs), and investigating combined sewer overflows (CSOs).

The USEPA added the ability to explicitly model the hydrologic performance of specific types of low-impact development (LID) devices such as porous pavement, rain gardens, green roofs, street planters, rain barrels, infiltration trenches, and vegetative swales. LIDs are used a part of best management

practices (BMPs) for reducing runoff and wet-weather pollutant loadings. A SWMM model can be applied to accurately represent virtually any combination of green infrastructure within a subcatchment area. The LID application of SWMM provides insight on the effectiveness of managing stormwater and the impact on CSOs and SSOs.

3.1.2 SWMM ADVANTAGES

SWMM has several advantages that make it one of the leading sewer system analysis programs. A SWMM model can be of unlimited size. While the more nodes, links, and subcatchments in a model increase the simulation time, there is no upper limit to the number of nodes, links, or subcatchments in a model.

The hydrologic portion of SWMM can simulate temporal variations in precipitation, infiltration, deep percolation into groundwater aquifers, and runoff through non-linear reservoir routing. SWMM can also simulate water quality in runoff through buildup and wash-off parameters.

Other hydraulic models compute the hydraulics of the collection system using the kinematic equation. While SWMM has the capability to compute simple hydraulics with the kinematic equation, it can also simulate complex hydraulics by computing a numerical solution to the full dynamic wave (St. Venant) equation. This allows SWMM to model various flow regimes, such as backwater, surcharging, and reverse flow. SWMM is preloaded with many different standard closed conduit and open channel shapes and has the ability to allow the user to create unique cross-sections for natural channels or other unique conveyance pathways. Users can also specify dynamic controls in the system such as gates or valves opening or closing in real-time.

3.2 PURPOSE OF THE MODEL

Before creating a model it is essential that the purpose of the model is clearly defined. In particular it is necessary to understand the information required to develop a model as well as the required results from the model coupled with the locations at which that information is required.

The primary goal of the Lakewood modeling project is to develop an updated computer model of the current sanitary sewer system for the City. The model is the primary tool used to study and evaluate the hydrologic and hydraulic performance of the City's sewer collection system and to explore improvement alternatives. The City established the following requirements and objectives for the model to meet the project goals:

- The model engine will be the USEPA SWMM 5.0 hydrologic and hydraulic model
- The new model will be developed using existing sewer maps and collecting field data

- All City-owned sanitary sewers eight-inches in diameter and greater will be modeled in SWMM
- The model will be calibrated and verified for both dry- and wet-weather flows using data supplied from the City's flow monitoring network placed in 2011
- The model will be used to predict the frequency and volume of discharges at the outfalls to the environment for a typical year simulation
- The model will be used to provide the basis for designing improvement alternatives to limit CSOs to an acceptable level as determined by the Ohio Environmental Protection Agency (OEPA)

The approach to the new model development conforms to these objectives and standards. Operating under the previously defined objectives, the appropriate level-of-detail model was selected based on the intended purpose of the model and the information required from it.

3.3 LEVEL OF DETAIL

The City committed to a comprehensive model of the collection system. An important decision regarding the model's level-of-detail was made prior to beginning any field work since the level-of-detail can influence the location and number of flow monitoring locations. The City decided that because of inadequate historical data that the comprehensive model would contain a great level-of-detail concerning the physical collection system. Data collected for the model would also serve as the most complete sewer mapping experience ever undertaken by the City. Models generally fall into one of three level-of-detail categories:

- Skeletal Planning Model
- Drainage Area Planning Model
- Detailed Drainage Model

Because of decision made by the City, the level-of-detail contained in the sewer system model is consistent with that of a Detailed Drainage Model. For completeness in this report, the Skeletal Planning and Drainage Area Planning Models are discussed in Section 3.3.1 and Section 3.3.2, respectively. The Detailed Drainage Model is presented in Section 3.3.3. It should be noted that many models use a combination of levels-of-detail which allows detail to be added only in those areas where problems exist or where critical sewer hydraulics require increased detail.

3.3.1 SKELETAL PLANNING MODEL

The Skeletal Planning Model is the coarsest level-of-detail. This type of macro or planning model has specific objectives including:

- Overall assessment of the effects a major new development on the trunk sewers in a catchment

- Initial evaluation of the options under consideration for major changes to the sewer network
- Understanding of the operation of specific sections of a sewer where reverse flows or other phenomenon that cannot be understood without modeling may be present
- Representation of a trunk sewer system or interceptor sewer system without needing to model exactly the layout of the sewer systems that connect into them

Skeletal Planning Models are not adequate for detailed modeling of flooding within a catchment or for drainage area studies, which require more detailed models.

3.3.2 DRAINAGE AREA PLANNING MODEL

A Drainage Area Planning Model is an intermediate level-of-detail model. This type of model is used to give an overview of a specific drainage area. A Drainage Area Planning Model is a preliminary planning tool used to:

- Identify potential hydraulic problems within a drainage area, including flooding areas, capacity restrictions, and reverse flows
- Identify the need for possible planning-level hydraulic capacity improvements
- Assess the impact of proposed developments

A Drainage Area Planning Model would include known problem areas, particularly known flooding and overflow areas with attention being given to low lying manholes or gullies.

3.3.3 DETAILED DRAINAGE MODEL

A Detailed Drainage Model provides the highest level-of-detail in the model. It is used for detailed investigations and detailed design improvement alternatives. Areas of greater detail would correspond to the specific problem areas, locations of potential hydraulic capacity improvements, and any portions of the sewer network (e.g. proposed pump installations) that may be affected by proposed system improvements. A Detailed Design Model typically includes most of the manholes in the areas affected by problems or the extent of proposed improvement alternatives. The level-of-detail in the City's collection system model is consistent with that of a Detailed Design Model.

3.4 COMPLEXITY

The City's collection system is extremely complex. The City's sewer collection system contains approximately 393,500 linear feet of sanitary sewers, 348,000 linear feet of storm sewers, and 133,500 linear feet of combined sewers serving the nearly 52,000 City residents.

Almost all of the sanitary sewers in the City were constructed in an “over/under” (O/U) configuration where the storm sewer was constructed directly above the sanitary sewer and only one manhole to access both pipes. O/U sewers were built predominantly during the 1920s and 30s although invert plate sewers were installed until the 1950s. This type of sewer is not known to exist anywhere else in the country other than in northeast Ohio. An invert plate in the “over” sewer allows access to the “under” sewer. There are a few isolated streets with separate trench sanitary sewers and at least two streets with O/U sewers where the sanitary sewer is above the storm sewer. The eastern 25 percent of the City is primarily combined sewers, although there are combined sewers on isolated streets in the western portion of the system as well.

The sanitary and combined collection systems are predominantly vitrified clay pipe (VCP) with brick and mortar manholes. Larger trunk sewers in the City adhere to the City of Cleveland’s standard egg-shaped cross sections and most are constructed of brick with integral brick manholes. Also scattered throughout the City are larger diameter storm and sanitary sewers constructed of segmented loose laid tile pieces which require compressive soil forces to maintain their integrity. These sewers are found in both circular and egg-shaped cross-sections.

3.4.1 INTERACTION BETWEEN SYSTEMS

In O/U manholes, a trough shaped plate is laid across the storm sewer invert from the upstream conduit to the downstream conduit to convey storm water. The invert plate is grouted into place so storm water cannot enter the sanitary sewer below. In order to access the sanitary sewer, the invert plate has to be physically pried open, breaking all the concrete grout. Maintenance crews leaving the manhole must re-grout the invert plate or it becomes a large inflow source during subsequent precipitation events.

The O/U configuration of the sewer collection systems leaves the “under” sewer extremely susceptible to I/I. Whatever joint sealing compound was originally used has deteriorated, so today, storm water can leak out of joints in the storm sewer, through the permeable backfill, and infiltrate the sanitary sewer joints.

3.4.2 SPECIAL HYDRAULIC STRUCTURES

To control flows within the City’s collection system, several special hydraulic structures have been constructed over time. Section 2.8 provides additional detail on some of the special hydraulic structures discussed in this section.

Sewer system overflows are one of the most prevalent hydraulic structures in the City’s collection system. Currently, the City has nine permitted overflows where sanitary sewerage could discharge to the environment. The overflows were designed to convey all dry-weather flow (DWF) to the wastewater treatment plant (WWTP). In wet-weather, the overflows limit the amount of wet-weather flow

(WWF) to the WWTP with the remaining flow being discharge to the environment.

Leaping weirs are present throughout the City's collection system. A leaping weir is designed such that a weir is constructed in the bottom half of a sewer pipe just downstream of a bottom orifice. The leaping weir configuration allows DWF to drop through to a sanitary sewer below but during wet-weather, flows that exceed the depth of the weir are passed downstream in a storm sewer. Not all bottom orifices in the City's system are constructed with a leaping weir just downstream of the orifice. Without a leaping weir in place, flows bypass the orifice more frequently.

Side-flow weirs were constructed at specific locations within the collection system. A weir on the side of a junction chamber allows DWF to be conveyed to the WWTP. In wet-weather, flows topping the weir are conveyed in a sewer to an outlet at the Rocky River or Lake Erie.

3.4.3 NORTHEAST OHIO REGIONAL SEWER DISTRICT SEWERS

The City of Lakewood shares a border with the City of Cleveland along W. 117th St. The Northeast Ohio Regional Sewer District (NEORS) provides sanitary sewer service for the City of Cleveland among other municipalities in northeast Ohio. There are several locations along W. 117th St. where the Lakewood sewers interact with the NEORS sewers.

NEORS owns and maintains several sewers that run from southwest to northeast under Berea Road at the southern edge of Lakewood. One of these sewers is a 108-inch diameter deep interceptor sewer which bears the NEORS designation, "Northwest Interceptor" (NWI). At the intersection of Berea Rd. and W. 117th St., the NWI turns north and follows the east side of W. 117th St. to Edgewater Dr., where it turns east to the NEORS Westerly WWTP. NEORS also owns, operates, and maintains a 60-inch diameter combined sewer that flows southwest to northeast under Berea Rd. at the intersection of Berea Rd. and W. 117th St., the 60-inch combined sewer flows into a junction chamber. A weir in the junction chamber at Berea Rd. and W. 117th St. regulates DWF to the east, but during wet-weather, flow from the 60-inch combined sewer overtops the weir and enters into the Lakewood owned, maintained, and operated 108-inch combined sewer which runs from south to north on the west side of W. 117th St.

Lakewood's sewers interact with NEORS sewers at two more locations on W. 117th St. Flow continues north in the Lakewood 108-inch combined sewer from Berea Rd. to Detroit Avenue where a weir regulated CSO from NEORS's NWI connects to Lakewood's sewer system. Immediately downstream of the weir in the NWI, flow passes a hydrobrake control structure where the pipe diameter changes from a 108-inch to a 30-inch diameter. Flow continues north in the Lakewood sewer to Lakewood's own flow regulator, south of Lake Avenue. In

this regulator, a side-flow weir passes DWF to a drop structure which flows back into Lakewood’s sanitary sewers tributary to Lakewood’s interceptor sewer which is known to have capacity limitations in the far upstream sections. At Lakewood’s flow-regulator on W. 117th St. south of Lake Ave., WWF that tops the weir flows north to yet another junction chamber owned and operated by NEORSD. In this regulator, a side-flow weir passes DWF to the NEORSD sewer system. WWF overtopping the weir flows through a 93-inch sewer to NEORSD’s permitted CSO (CSO-071) at Lake Erie.

A study was performed for the NEORSD Westerly WWTP under the Ohio Department of Transportation’s “Central Viaduct” project (CUY-90-14.90, PID 77332/85531). The Westerly Modeling Report from the CUY-90-14.90 project is included in Appendix B of this report for reference and convenience. The Westerly Modeling Report identified several locations where flow monitors were installed to estimate the interaction between the Lakewood sewer collection system and the NEORSD system. **Table 3.1** provides a summary of the locations of flow monitors identified in the Westerly Modeling Report.

Table 3.1: NEORSD Flow Monitor Locations near Lakewood

Flow Monitor	Location	Description
Lakewood	Lake Ave. and 117 th St.	Regulator DWF Outlet
NW4-D	Edgewater Dr. and 117 th St.	Regulator DWF Outlet
NW4-I	117 th between Lake and Edgewater	Regulator Inlet
NWI-2	1601 117 th St.	Interceptor
NWI-T1	11642 Detroit Ave.	Trunk Sewer
WST-2	Berea Rd. and 117 th St.	Interceptor
WST-3	11600 Berea Rd.	Interceptor
WST-5	Lake Ave. and 116 th St.	Interceptor
WST-T1	2181 117 th St.	Trunk Sewer

The Westerly Modeling Report has limited application for the Lakewood sewer system, except at the locations where the two systems interact. Unfortunately, even after multiple attempts, data from the NEORSD Westerly modeling study were not able to be obtained.

3.5 DISCRETIZATION

SWMM represents a sewer system as a series of individual nodes and links. Model nodes may represent manholes, outfalls, junction chamber, diversions structures, or storage units. Model links, which connect two nodes together, represent conduits, pumps, orifices, weirs or outlets. Subcatchments represent drainage areas and are used to compute overland flow (runoff) from excess precipitation. The Lakewood SWMM model contains 3,623 nodes, 1,263 subcatchments, and 4,737 links.

3.5.1 NODES

Nodes are natural points of discretization for a SWMM model. They are used as input locations for external inflows and receive runoff from catchment areas. The Lakewood system model contains 3,623 nodes divided amongst junctions, outfalls, and storage nodes as follows:

- 3,582 Junctions
- 40 Outfalls
- 1 Storage Node

3.5.2 SUBCATCHMENTS

The sewer subcatchments represent the service area tributary to the City's sewer system and are used to determine the dry- and wet-weather flows loaded to the model nodes. The Lakewood system model contains 1,263 subcatchment areas ranging in size from approximately 0.125 acres to 43 acres. The average subcatchment size is 2.46 acres with a standard deviation of 2.16 acres.

Subcatchments were delineated based on the parcel boundaries obtained from the Cuyahoga County geographical information system (GIS) database. The project team chose to delineate based on parcel boundaries because previous experience showed that nearly 50 percent of the I/I response may be contributed to private property sources. Rather than traditional topographic tributary areas contributing stormwater runoff directly to the public sewers, the I/I response in Lakewood's collection system was determined to be closely related to the dry-weather service area (e.g. parcel boundaries). In addition, because the City of Lakewood is extremely densely populated and developed, parcel boundaries are an appropriate substitute to approximate topographic drainage boundaries. **Figure 3.1** shows an example of the subcatchment delineation by parcel boundaries and illustrated by multi colored polygons. The catchment boundaries between manholes were delineated based on parcel boundaries, approximately halfway between the manholes. In most cases, one parcel equates to one consumer and has one loading point to the sewer system. Special cases, such as one parcel containing multiple buildings (with sewer service) or one building occupying multiple parcels; were investigated and delineated on a case-by-case basis. For areas containing parallel sewer mains with different sizes, the subcatchments were delineated based on the smaller sewer pipes in most cases, because relief sewers typically do not have service connections.

\\mtr-fs1\mtr-vol1\2011\1101601\REPORTS\Ch-3\Figures\Figure 3-01 Subcatchment Delineation.mxd

3.5.3 LINKS

Links are not natural discretization points in a SWMM model, rather they connect nodes. Links convey external inflows and runoff loaded at the nodes. The Lakewood system model contains 4,737 links divided amongst conduits, pumps, orifices, and weirs as follows:

- 3,663 Conduits
- 1 Pump
- 1,022 Orifices
- 51 Weirs

Almost any sewer shape can be modeled in SWMM including non-circular shapes found throughout the Lakewood collection system. Many of the sewers in Lakewood were built according to the City of Cleveland Standard Egg-Shape. The Lakewood SWMM model represents these sewers as well as vertical ellipse sewers, sewers filled with sediment, and horizontal ellipse sewers.

3.6 INPUT DATA

Input data can be collected from a number of different sources including historical records, field surveys, and data collection devices. The level of accuracy of the input data will directly influence the results of the final model. In some cases inaccuracies in the input data will have little impact on the accuracy of the final model results while in other cases inaccuracies in the input data will be highly significant. It is often possible (although relatively expensive) to increase the data collection effort in the form of extensive plan research and field data collection so that the problem areas are scrutinized. While time consuming and potentially costly, extensive data collection efforts can save significant amounts of time and budget when it comes to data input and model calibration.

The work associated with field survey and data collection for the City's sewer collection system grew substantially from the effort that was anticipated because of the complexity of the sewer system, the lack of as-built records, the continual modifications made to the system over time, and some unique construction features that were challenging to find, analyze, and document. To ensure the model accurately reflects the interconnectivity and characteristics of the physical sewer system, a number of requests for information precipitated a detailed search of the sewer drawings in the City's records, and required repeated field investigations to investigate where the interconnectivity was not understood and physical characteristics of the system were ambiguously documented. The model representation of the physical sewer system was further complicated by the interaction in the O/U sewers. The field investigations and records research revealed 17 undocumented potential overflow locations expanding the number of discharge points that could release untreated sewage from the nine permitted overflows to 26 potential overflows. It is estimated that the resources devoted to the data collection for the City's

system-wide sewer model is the most exhaustive data collection effort ever completed by the City on their collection system.

3.6.1 NODE PARAMETERS

The basic node data needed to build the City's SWMM model is as follows:

- Node invert elevations
- Node depths/ground elevations
- Pipe offsets/elevations at each node

In general, most of the required node data was available from existing records. Care was taken to check the continuity of the data records. Because different elevation data are used for surveying (e.g. NAVD29 or NAVD88), occasionally node elevations were converted from one datum to another for consistency in the model. Where data was missing, field visits and surveys were required. The City's crews collected information such as pipe configuration, pipe size, manhole depth, and closed-circuit television (CCTV) footage when requested.

3.6.2 LINK PARAMETERS

The basic link data needed to build the City's SWMM model is as follows:

- Details of the sewer network and connectivity
 - Upstream Node
 - Downstream Node
- Link Sizes
 - Pipe Diameter
 - Weir Height and Length
 - Orifice Diameter
- Link Invert Elevation
 - Upstream Invert
 - Downstream Invert
- Manning's Roughness Coefficient

In general, most of the required link data was available from existing records. Care was taken to check the continuity of the data records. Because different elevation data are used for surveying, occasionally link invert elevations were converted from one datum to another for consistency in the model. Where data was missing, field visits and surveys were required.

Data not readily obtained from plans or site visits (e.g. Manning's roughness coefficient) can be estimated from published sources or the condition of the pipe. In addition to estimating the roughness coefficient of the pipe, the condition of the pipe can have a significant impact on the I/I potential. Pipe condition data from CCTV records may be used to determine the roughness coefficient and I/I potential of pipes. Where no data is available values may be estimated based on the pipe material and age.

Sediments may reduce the cross-sectional area of the pipes limiting the capacity. Sediment depth data may be obtained from CCTV surveys, sewer flow monitoring reports, or from operational records.

3.6.3 PRECIPITATION DATA

A variety of sources may be utilized to gather precipitation data for the model. Data are typically available from sources such as:

- Government Institutions
 - National Oceanic and Atmospheric Administration (NOAA)
 - National Weather Service (NWS)
 - State Climate Offices
- Precipitation Gages
 - Site-specific Rain Gages
 - Community Rain Networks
- Synthetic Precipitation Events
- Radar Rainfall

Historical precipitation records may come as long-term time series from sources such as NOAA and the NWS or records may be of a shorter temporal horizon from instruments installed specifically for the purposes of the modeling project. For calibration efforts, it is desirable to obtain precipitation records on the order of five to 15-minute resolution. Precipitation gage measurements were used for calibration purposes of the Lakewood system model. Rainfall time series were checked for missing data to verify the completeness of the data. The precipitation data used in the City's collection system model is discussed in detail in Chapter 4 and Chapter 6 of this report.

3.6.4 SUBCATCHMENT PARAMETERS

The basic subcatchment data needed to build the City's SWMM model is as follows:

- Area
- Width (or Flow Length)
- Slope
- Percent Impervious
- Manning's Roughness Coefficient
- Surface Storage Depth
 - Pervious
 - Impervious
- Infiltration Parameters

In general, most of the required subcatchment data was available from existing records. Area was obtained from the subcatchment delineation process, width was calculated as the area divided by the flow length from the hydraulically most

remote location of the subcatchment, percent imperviousness was determined from ortho-imagery, Manning's roughness and surface depression storage were estimated by referencing tables for the type of land cover. Infiltration parameters were estimated by referencing tables for Horton infiltration parameters such as maximum and minimum infiltration rates for the specific type of soil present in any particular area of the City. Typically found from the county's soil survey information or from the United States Geological Survey (USGS), soil data is highly site specific and may vary greatly over a study area.

3.6.5 DRY-WEATHER FLOW PARAMETERS

DWF is the combination of domestic, commercial, and industrial wastewater flow in the sanitary or combined sewer system during periods in which the sewer system is not influenced by precipitation in the form of I/I. The two constituents of DWF are base wastewater flow (BWF) and groundwater infiltration (GWI). The SWMM model has specific input parameters to replicate observed DWF, which are discussed in detail in Chapter 5 of this report.

3.6.6 WET-WEATHER FLOW PARAMETERS

WWF in a sanitary or combined sewer collection system is the combination of domestic, commercial, and industrial wastewater flow with the addition of rainfall derived I/I. The SWMM model has specific input parameters to replicate observed I/I and WWF in collection system models. Wet-weather parameters are discussed in detail in Chapter 6 of this report.

3.7 MODEL ANALYSIS AND APPLICATION

Once constructed and calibrated, the SWMM model is a powerful tool for system analysis. The model results can provide insight to complicated hydraulics that may otherwise not be understood and identify potentially unknown problem areas in the system. The model can also be used to anticipate the system response to future events.

3.7.1 DRY-WEATHER FLOW ANALYSIS

The first step to calibrating the model after the input data has been entered into the model is DWF analysis. The general purpose of dry-weather flow analysis is to characterize the sewer system's behavior when it is not under the influence of precipitation. The analysis of dry-weather is the basis for all other model calibration efforts and applications. Dry-weather flow calibration is discussed in detail in Chapter 5 of this report.

3.7.2 WET-WEATHER FLOW ANALYSIS

The general purpose of wet-weather flow analysis is to characterize the sewer system's response to precipitation. The USEPA's Sanitary Sewer Overflow Analysis and Planning (SSOAP) Toolbox is the primary tool used to perform the

WWF analysis. Wet-weather flow model calibration is discussed in detail in Chapter 6 of this report.

3.7.3 CONTINUOUS SIMULATION

The general purpose of continuous simulation is to characterize the sewer system's response to precipitation and recovery before subsequent precipitation events. The continuous simulation of the Lakewood system model is discussed in detail in Chapter 8 of this report.

3.7.4 TYPICAL YEAR APPLICATION

The typical year precipitation record was simulated in the calibrated model to determine the number of overflow activations and volume discharged during a typical precipitation conditions. The typical year model simulation results are discussed in detail in Chapter 8 Section 4 of this report.

3.7.5 PROPOSED IMPROVEMENTS APPLICATIONS

The model was used to simulate system capacity after proposed improvement scenarios to the City's West End near Detroit Avenue Extension and West Clifton Boulevard. Being able to predict the impact of improvements on the system is extremely useful and can potentially save significant amounts of money that would otherwise be sunk into constructions projects that would have little positive impact on the system. It is anticipated that the calibrated model will be used to analyze future proposed improvements as well such as high rate treatment at the WWTP, the Edgewater Sewer Separation and the Pilot Study in the CSO-052 area.

CHAPTER 4 –FLOW AND PRECIPITATION MONITORING DATA

4.1 INTRODUCTION

The City of Lakewood (City) collected depth, velocity, flow, and precipitation data to calibrate the collection system model. The City installed, maintained, and collected data from 50 flow monitors and three rain gauges. The flow data collection ran from April to August of 2011. Dates vary depending on when the flow monitor was installed. Data collection for the precipitation gauges began May 5, 2011. All flow monitors within the City were installed to collect dry- and wet-weather flow data. The flow and rainfall information was used to adjust the model's parameters to match its calculated output to the observed flow data during model calibration.

4.2 PRECIPITATION DATA

The City installed three Sigma 111 rain gauges to measure precipitation. The rain gauges use a “tipping bucket” to record incremental precipitation. Precipitation is collected and funneled into one of two buckets situated on a “teeter-totter” within the gauge housing. When one one-hundredth of an inch of rain falls, the bucket teeters over and while it drains, the other bucket collects precipitation. Each time the buckets tip, a pulse is sent to the monitor. The accuracy of precipitation data was ± 0.5 percent for 0.5 inches per hour. The rain gauges were programmed to report collected data in 10-minute increments and were downloaded manually approximately every two weeks.

The rain gauges were located at three locations across the City to establish a spread that would capture the spatial and temporal variance of precipitation. Due to ridge lines and lake effects, the southern portion of the City sometimes experiences more intense rainfall than the northern portion. The rain gauge locations are shown in **Figure 4.1** and listed in **Table 4.1**. The City recorded precipitation at the wastewater treatment plant (WWTP) during 2013. The WWTP gauge was used to verify the typical year continuous simulation model by simulating the calendar year 2013. Details of the continuous simulation are provided in Chapter 8 of this report.

Table 4.1: City of Lakewood Rain Gauge Locations

RG Name	Location	Recording Frequency (min)	Data Collection Dates
CityHall_RG ¹	Lakewood City Hall Detroit Ave.	10	05/05/2011-08/08/2011
FireStation_RG ¹	Fire Station No. 1 Madison Ave. at Warren Rd.	10	05/05/2011-08/08/2011
Lincoln_RG ¹	Lincoln Elementary Clifton Blvd. at Lakeland Ave.	10	05/05/2011-08/08/2011
WWTP_RG ²	WWTP Valley Pkwy.	15	01/01/2013-12/31/2013

¹Installed as part of the City's Long-Term Control Plan and used for calibration

²Used for continuous simulation of calendar year 2013 and not used for calibration

The CityHall_RG did not record any precipitation from May 18, 2011 through June 7, 2011. For the CSO areas located between the CityHall_RG and the FireStation_RG the rain data was averaged between the CityHall_RG and the FireStation_RG to give a better representation of the rain data across the area. During the CityHall_RG rain gauge drop out data from the FireStation_RG was used.

All three rain gauges were used to calibrate the SWMM model. CityHall-FireStation-Average_RG was used for the drainage areas in the eastern portion of the City. FireStation1_RG was used for drainage areas in the southern and central portions of the City and Lincoln_RG was used to calibrate the sewers in the northern and western portions of the collection system. The precipitation hyetograph showing the raw data of the rain gauges is presented in **Figure 4.2**. The corrected data for CityHall_RG is shown in comparison to the raw data for the CityHall_RG in **Figure 4.3**.

Figure 4.2: Precipitation Hyetograph for 2011 Lakewood Rain Gauges

Figure 4.3: Precipitation Hyetograph for Corrected CityHall_RG

4.3 NUMBER OF PRECIPITATION EVENTS

At least three significant precipitation events are required to calibrate the model; however, typically five to six events are selected. A significant precipitation event is defined as:

- The total depth should be greater than 0.2 inches.
- The range of total durations of the rainfall should vary. Ideally one storm should have a duration equal to $\frac{1}{2}$ of the time of concentration of the system, one storm equal to the time of concentration, and the third more than twice the time of concentration.
- The rainfall intensity should be greater than 0.24 inches/hour for more than 4 minutes.
- The period between events should be sufficient for the flow to return to dry weather conditions

The rain gauge data was reviewed to identify all the precipitation events during the flow monitoring period from May 5, 2011 through August 8, 2011. Fifteen (15) events were identified during the precipitation monitoring period. Each rainfall event was reviewed independently; however, several guidelines were used in grouping the data. These include:

- Events with total rainfall depth less than 0.20-inch were not used (16 events)

- Events that occurred less than four hours apart were classified as one precipitation event
- Post-event precipitation totaling less than 0.01-inch for the six hours after the storm were neglected
- Events were posted on the day the peak intensity occurred

4.4 PRECIPITATION EVENT CLASSIFICATION AND SELECTION

The rainfall events were classified using a partial duration approach that classifies an event by the most severe portion. “Frequency Atlas of the Midwest Rainfall” by Floyd A. Huff and James R. Angel was used to classify the events. The applicable excerpt from the document can be found in Appendix C.

The eight storm events listed in **Table 4.2** were averaged between all three rain gauges and selected for calibrating and verifying the hydraulic model. The criterion preferred for the selected storms was a peak 1-hour rainfall of 0.25 inches or more. The table lists the average values of the observed rain gauges and additional data for eight rainfall events that occurred within the monitoring period. The antecedent dry period time is the number of hours since the previous rainfall of 0.01 inches or more. The return period classification is based on comparing the peak 10-minute and total volumes to the Rainfall Frequency Atlas of the Midwest. Each storm event was classified according to the highest return period. For example, Event 6 was classified as a 50-year event instead of a 25-year event.

Table 4.2: Average Precipitation Events Based on Rain Gauge Data

Event	Date	Antecedent Dry Period (hours)	Storm Duration (hours)	Average Peak 10-min (inches)	Average Peak 1-hr (inches)	Total Rainfall (inches)	Return Period (Total Volume)	Return Period (Peak 1-hr)
1	5/14/11	9.28	57.00	0.20	0.33	1.28	2-mo 72-hr	<2mo 1-hr
2	5/25/11	41.08	12.25	0.60	1.12	1.55	9-mo 12-hr	2-yr 1-hr
3	5/29/11	15.33	0.50	0.35	0.56	0.56	6-mo 30-min	2-mo 1-hr
4	6/7/11	204.33	0.94	0.27	0.62	0.62	3-mo 1-hr	3-mo 1-hr
5	6/19/11	70.39	6.72	0.50	0.88	1.03	4-mo 6-hr	6-mo 1-hr

7	7/22/11	83.00	2.78	0.72	0.94	0.97	6-mo 3-hr	1-yr 1-hr
8	7/23/11	6.33	5.28	0.21	0.34	0.70	<2-mo 6-hr	<2-mo 1-hr

4.5 FLOW MONITORING PROGRAM

The City utilized 50 Sigma 910 Portable Area Velocity Flow Monitors for the purposes of calibrating the model. The City installed and maintained these temporary flow monitors to measure sewage flow rates during dry- and wet-weather.

The Sigma 910 is compact and lightweight which makes it easily fit in a variety of applications such as sewer monitoring. The Sigma 910 monitors are equipped with a submerged area/velocity pressure transducer sensor to measure the depth of the flow in the sewer. The flow depth is converted into a cross sectional area (A) based on the size and shape of the sewer. The submerged area/velocity sensor uses Doppler technology to measure the velocity (V) of the liquid in the sewer. From these two measurements a flow (Q) can be calculated ($Q = A * V$). The flow monitors were programmed to report collected depth, velocity, and flow readings every 10-minutes. Flow data was collected approximately every two weeks by City personnel using a laptop computer. Flow data for each monitor is presented in Appendix A.3. The locations of the flow monitors are shown on **Figure 4.4** and **Table 4.3** lists the exact location of the flow monitors and the purpose for the location selection. The flow monitor locations were determined so that the monitors could measure the dry-weather sanitary flows throughout the City. A few flow monitors had other purposes such as CSO-052_M011 which was installed to measure flow coming into the City of Lakewood from the City of Cleveland.

Data analysis began with verification of the flow monitor setup information. The installation information was reviewed with City personnel. The monitoring plan was based on historical record information, and in some cases the actual pipe sizes and shapes were different than the records. Some flow monitors were not placed in the planned locations because the original placement location was not accessible or was not configured as the record information indicated.

The City personnel prepared a Flow Monitor Site Data Sheet for each monitor location at the time of installation. Information included flow direction in and out of the manhole, the pipe which contained the flow monitor, and any other pertinent information. The Flow Monitor Site Data Sheet are included in Appendix D. Visits to the flow monitoring sites were made approximately every two weeks to measure flow depth and velocity, recalibrate the depth sensors, check the condition of the electronic equipment, and download the recorded flow data. Notes were made to the appropriate Flow Monitor Site Data Sheet at the time of the observation regarding the monitor data, measurements recorded at the time of observation, and the condition of the monitor.

Data from three flow monitors installed in 2010 for the Phase I Flow Data Analysis were used for this study in the efforts to calibrate CSO-059C. CSO-056_M018 was reinstalled in 2012 since the 2011 data was not usable and the monitor location was essential to calibrating CSO-056.

4.6 FLOW MONITORING DATA REVIEW

The flow monitoring data was reviewed to determine the quality of the data with respect to using it for model calibration and validation. Hydrographs were prepared for each month showing depth, velocity, flow, and precipitation data. Examples of monthly and single-event hydrographs are shown in **Figures 4.5** and **4.6**, respectively.

Figure 4.5: Example Depth and Velocity Monthly Hydrograph

Figure 4.6: Example Single-Event Hydrograph

4.7 FLOW MONITORING DATA QUALITY ANALYSIS

The flow monitoring data was reviewed for indicators of data quality. Each quality indicator is described in Section 4.7.1 through Section 4.7.4. Hydrographs were used to evaluate:

- Data gaps in velocity and/or depth data
- Data drifting
- Synchronized movement of the velocity and depth readings
- Proportional movement of the velocity and depth readings

4.7.1 DATA GAP ANALYSIS

The flow monitoring data was checked for data gaps at each monitoring site. Data gaps can be caused by low battery power, monitor servicing, temporary monitor removal for pipe cleaning, monitor submergence, sensor dislodgement or monitor malfunction.

Figure 4.7 shows a data gap from May 13 to June 9 for CSO-002_M043. The Flow Monitor Site Data Sheet indicated the no data had been logged since May 13 so the battery was changed during the May 25 site visit. The subsequent site visit revealed that the monitor was still not logging data so at that time the canister was replaced. In this case the monitor began working after the canister replacement but dropped out again on June 23. The crews were not able to get the monitor to work again after that.

Figure 4.7: Data Gap Example

Data gaps under-estimate flows because the program will calculate zero flow for the missing time period. If the gap occurs during a wet-weather event, storm flow data will be under-calculated and the data cannot be used for calibration. This could lead to incorrect conclusions about the effectiveness of proposed rehabilitation techniques.

4.7.2 DATA DRIFT ANALYSIS

Data drifting is a common problem in which there is a slow and steady movement of the flow data away from the flow monitor calibration point. Using the hydrograph, the dry-weather flow was reviewed to verify that the average dry-weather flow generally remained consistent throughout the monitoring period. Data drifting will produce inaccurate flow data readings. The hydrographs shown in **Figure 4.8** is typical of the sites which showed no evidence of drifting. The hydrograph in **Figure 4.9** shows an example of data drifting for CSO-056_M051. From June 25 to June 28 the difference between depth and velocity is constant but then the depth begins to increase while the velocity continues the same diurnal pattern.

Figure 4.8: Dry-Weather Flow Hydrograph

Figure 4.9: Data Drift Flow Hydrograph for CSO-056_M051

4.7.3 DEPTH AND VELOCITY DATA ANALYSIS – SYNCHRONIZED RECORDING

As a check on the operational status of the depth and velocity sensors, the movements of the depth and velocity data were reviewed to see that they began responding to rain events at approximately the same time. An offset in the response of the depth or velocity to precipitation of more than one recording period would indicate a problem with the monitor and bring the viability of the

data into question. **Figure 4.10** is typical of the flow monitor data. No synchronization issues were observed at this monitor.

Figure 4.10: CSO-059C_M030 Depth and Velocity Data Synchronization, June 2011

4.7.4 DEPTH AND VELOCITY DATA ANALYSIS – SCATTERGRAPH RELATIONSHIP

An additional check on the operational status of the sensors was a review of the proportionality of the movement for the depth and velocity readings. Debris in the flow stream (i.e. rags, sediment, etc.) can impair the ability of both the depth and velocity sensors to measure accurately. **Figure 4.11** is the scattergraph for CSO-059_M028 of depth versus velocity. On average, the velocity and depth moved proportionately. There is no backwater condition at this site.

Figure 4.11: Example Scattergraph – CSO-059_M028

4.8 DRY-WEATHER FLOW DATA ANALYSIS – CONSISTENCY

The consistency of flows during dry-weather was reviewed to assess the ability of a model to reproduce the flows. For the data available from the dry days, plots of flow rate versus time were reviewed. **Figure 4.8** in Section 4.7.2 shows the dry-weather hydrographs for CSO-059_M028. The range of flows versus the average flows on fits a reasonable envelope. The dry weather hydrographs were within ± 25 percent of the average flow. A 25 percent error is higher than the recommended 10 percent in the WaPUG standards and would suggest that the dry-weather data quality is average quality data.

4.9 IRRECONCILABLE MONITOR DATA

Consistency and quality of the flow data varied from monitor to monitor therefore each monitor was analyzed separately. Based on the flow monitoring data review it was determined that some monitor data was affected by the conditions described in Section 4.7.1 through Section 4.7.4. Some adjustments were made to the flow monitor data to correct for data drifts and smaller data drop outs. Some monitors had larger data drop outs, but were used for calibration as long as there were periods of dry-weather and wet-weather data that were usable. Monitors where the data drop outs were continuous or where the data had unexplainable variations were eliminated from the calibration process. A list of monitors excluded from the calibration and reason for excluding the monitor is included in **Table 4.4**.

Fifty flow monitors were installed for this study of which 21 flow monitors were excluded from the model calibration. In comparison, the 1978 study completed by Watermation, Inc. only used 10 flow monitors to collect flow data. Flow monitoring for the Long-Term Control Plan prepared by Metcalf and Eddy (AECOM) in 2003 utilized 21 flow monitors. Although 40% of the flow monitoring data was not usable, it is still the most comprehensive flow monitoring undertaken by the City at this time.

Table 4.4: Flow Monitors Excluded from Model Calibration

CSO	Monitor #	Location	Reason for elimination
CSO-002	46	Lake Road at Webb	Continuous data dropouts
CSO-002D	48	North side of Clifton at Webb	Continuous data dropouts
CSO-002E	50	Summit at Clifton	Continuous data dropouts
CSO-052	1	Lincoln north of Athens	Continuous data dropouts
	2	Lincoln south of Madison	Poor dry weather flow data
	3	Madison West of Lincoln	Inconsistent data
	5	Madison east of Morrison	Inconsistent data
	9	Madison at Spring Garden	Monitor only recorded data in July with data dropouts
	10	Fischer at Northland	Continuous data dropouts
	11	Riverside north of Naragansett	Poor dry weather flow data
	12	Riverside at Hillard	Continuous data dropouts

CHAPTER 5 – DRY-WEATHER FLOW CALIBRATION

5.1 DRY-WEATHER PERIOD

A variety of sources may be utilized to determine typical dry-weather flow (DWF) for the model. Data are typically available from sources such as:

- Population Estimates
- Water Usage Statistics
- Flow Monitoring

It is important to calibrate the model's DWF parameters prior to wet-weather flow (WWF) calibration. Accurate DWF data is required for collection system modeling as the DWF calibration serves as the foundation for WWF calibration. The first step to DWF calibration is to identify the dry-weather periods available for calibration. Once the periods are identified, periods with poor data should be eliminated from consideration for DWF calibration.

The City's flow monitoring period began in April, 2011. Flow monitors were removed from the system in August, 2011. Not all flow monitors were installed in April and some were pulled early in August while others were removed late in August. The locations of the installed flow monitors are shown in **Figure 5.1**. The City initially installed 50 flow monitors for data collection; however, 21 were not able to be used for DWF calibration. The period consistent across nearly all 29 flow monitors spans from May through July, 2011. For consistency in the model, it was desirable to calibrate the DWF for all flow monitors to the same period if possible. Several DWF periods were identified as possible calibration candidates including:

- June 01-07, 2011
- July 12-18, 2011

Most flow monitors collected good quality data for the July 12-18, 2011 period; therefore, this was the primary period used for DWF calibration. Several flow monitors did not collect good quality data during the July period and these flow monitors used other available DWF periods for calibration. Three flow monitors were installed during 2010 and used for DWF calibration. These monitors used the May 23-30, 2010 period for DWF calibration. **Table 5.1** presents the DWF periods used for calibration for each flow monitor.

Table 5.1: DWF Period Identified for Each Flow Monitor¹

Overflow Area	Monitor Name	Begin DWF Period (Date)	End DWF Period (Date)
CSO-002A	M044	7/12/2011	7/18/2011

¹Only flow monitors used for DWF calibration are shown here. For a list of all meters installed, see Figure 4.4 or Table 4.3 of this report.

²Meter installed in 2010 and used for calibration to avoid large uncalibrated areas in the model.

5.2 DRY-WEATHER FLOW

DWF is the combination of domestic, commercial, and industrial wastewater flow in the sanitary or combined sewer system during periods in which the sewer system is not influenced by precipitation in the form of infiltration and inflow (I/I). The two constituents of DWF are base wastewater flow (BWF) and groundwater infiltration (GWI). **Equation 5.1** establishes the relationship of BWF and GWI to DWF.

$$DWF = BWF + GWI \quad \text{Eq. 5.1}$$

The SWMM model has specific input parameters to replicate observed DWF. Since GWI is reasonably constant for a particular location over a relatively short temporal horizon, GWI is traditionally calculated as a fixed percent of the average DWF for the same period. For the Lakewood system model, GWI was assigned monthly variations. The monthly GWI patterns are discussed in detail in Section 5.3.

BWF changes on a shorter time horizon than GWI. The predictable temporal variation of BWF creates the well-known diurnal pattern in the sewer collection system. Typically the diurnal pattern shows a peak in water usage early in the morning as people prepare for work and a spike in the evening as people return from work and water usage in the house increases for cooking, etc. **Figure 5.2** shows a visual representation of the elements of DWF with the addition of rainfall dependant infiltration and inflow (RDII). RDII is discussed in detail in Chapter 6 of this report.

Figure 5.2: Flow Components

5.3 GROUNDWATER INFILTRATION CALCULATION

GWI is different from infiltration induced by precipitation because GWI is always present in the system. GWI varies spatially and temporally, potentially making it

difficult to identify. Typically, GWI is calculated as a percentage of the DWF determined from observed flow at flow monitor locations or at the wastewater treatment plant (WWTP). In the absence of measured data, a percentage of the known return rate of domestic water supply can be substituted into the model.

Domestic, commercial, and industrial contributions compose normal municipal wastewater flow streams. On average, 60 to 90 percent of the treated water distributed to domestic customers is returned to the WWTP from in-home use such as: appliances, showers, tubs, and toilets (Guadalupe-Blanco River Authority, www.gbra.org/documents/studies/caldwell/09-WastewaterFlows.pdf). The 10 to 40 percent of potable water not returned as wastewater is generally used for outdoors applications such as: lawn-water, gardening, or vehicle washing. **Figure 5.3** shows the typical municipal water cycle (flow rates shown for illustration purposes only and do not represent the City's water production or wastewater flow).

Figure 5.3: Municipal Water Cycle

The calculation to determine GWI flows in the SWMM model is shown in **Equation 5.2**.

$$GWI = \text{Baseline Value} \times \text{Baseline Pattern} \quad \text{Eq. 5.2}$$

Baseline Value is the average value of GWI and the *Baseline Pattern* is a monthly adjustment multiplier. The *Baseline Pattern* is discussed in detail in Section 5.5.1 of this report. The baseline GWI patterns computed for each flow monitor can be found in Appendix E.

5.4 BASE WASTEWATER FLOW CALCULATION

Generally, BWF follows predictable diurnal patterns for a given service area. BWF can be identified by:

- Land Use
- Service Area Size
- Service Area Growth/Development Rate
- Water Use Practices

A “typical” BWF calculation is represented by diurnal variations applied to small sewer areas (flow monitor tributary areas). The BWF for the SWMM model is determined by **Equation 5.3**.

$$BWF = Avg. Flow \times Monthly \times Daily \times Hourly \times Weekend \quad \text{Eq. 5.3}$$

Where *Avg. Flow* is the average flow value, *Monthly*, *Daily*, *Hourly*, and *Weekend* are multipliers to adjust the magnitude of the average flow value to create a diurnal pattern. Each term in Equation 5.3 is discussed in detail in subsequent sections of this report. The BWF patterns computed for each flow monitor can be found in Appendix F.

5.5 DRY-WEATHER FLOW TIME PATTERNS

Time patterns allow the model to control the predictable periodic variation of observed dry-weather wastewater flows. Dry-weather flow time patterns consist of a set of adjustment factors applied as multipliers to a baseline DWF flow rate (or pollutant concentration, for water quality modeling). The different types of time patterns include:

- Monthly
- Daily
- Hourly
- Weekend

Each average dry-weather flow value can have up to four unique patterns (multipliers) assigned to it. Only one of each type of dry-weather flow time pattern may be assigned to a dry-weather flow value. Each type of time pattern is discussed in detail in the subsequent sections of this report.

5.5.1 BASELINE TIME PATTERN

The Baseline Time Pattern is an optional time pattern whose factors adjust the baseline flow value on either an hourly, daily, or monthly basis, depending on the type of time pattern specified. GWI fluctuations are often represented by the Baseline Time Pattern used to account for variation in the baseline flow value. The baseline flow is the absolute minimum flow observed for the DWF period. The GWI (or baseline) pattern multiple increases the baseline value (>1) or

decreases the baseline value (<1). In order to maintain the desired minimum baseline value, the multiples should average approximately 1.0.

5.5.2 MONTHLY TIME PATTERN

The Monthly Time Pattern is an optional time pattern whose factors adjust the average flow value on a monthly basis. The Monthly Time Pattern can be used to fine tune the DWF calibration because typically, the BWF average value does not show large monthly deviations. The monthly pattern multiple increases the average value (>1) or decreases the average value (<1). In order to maintain the desired minimum monthly flow, the monthly multiples should average 1.0 over a 12-month period.

5.5.3 DAILY TIME PATTERN

Occasionally, a specific day of the week was observed to be consistently different than other days of the week. A Daily Time Pattern was used to account for this difference. The Daily Time Pattern is an optional time pattern whose factors adjust the average flow value on a day-of-the-week basis. The daily pattern multiple increases the average value (>1) or decreases the average value (<1). In order to maintain the desired minimum daily flow, the daily multiples should average 1.0 over a week-long period.

5.5.4 HOURLY TIME PATTERN

The Hourly Time Pattern is an optional time pattern whose factors adjust the average flow value on an hour-by-hour basis. The Hourly Time Pattern replicates the observed diurnal pattern quite well. The hourly pattern multiple increases the average value (>1) or decreases the average value (<1). In order to maintain the desired minimum hourly flow, the monthly multiples should average 1.0 over a 24-hour period.

5.5.5 WEEKEND TIME PATTERN

Occasionally, the weekday and weekend time diurnal patterns were observed to be consistently different. The Weekend Time Pattern is an optional time pattern whose factors adjust the average flow value on an hour-by-hour basis for weekend days only. The Weekend Time Pattern replicates the observed weekend diurnal pattern quite well. The weekend pattern multiple increases the average value (>1) or decreases the average value (<1). In order to maintain the desired minimum monthly flow, the weekend hourly multiples should average 1.0 over a 24-hour period.

5.6 DRY-WEATHER FLOW CALIBRATION

DWF was calibrated for each flow monitor to the period shown in **Table 5.1** (Section 5.1). In addition to the modeling parameters mentioned in Sections 5.2 through 5.5, field

data were used to calibrate the DWF model. The field data, calibration effort, and results are discussed in the following sections.

5.6.1 WATER CONSUMPTION DATA COLLECTION AND ANALYSIS

Individual household water billing (water consumption) records were utilized as the basis for generating DWF hydrographs in the DWF model simulations. The City's water billing record data were used to establish expected average DWF values at each modeled subcatchment area. Observed flow monitoring data were used to confirm average DWF flow rates generated from the water billing data.

To create needed DWF model inputs, water usage at the flow monitor basin level was calculated by correlating the water usage records to the model delineated catchments. The subcatchment water usage is the summation of all the individual parcel water usage within the delineated subcatchment. DWF baseline values were created for each flow monitor basin using average values obtained from the water consumption data.

5.6.2 DRY-WEATHER FLOW DATA ANALYSIS

Flow monitoring data were also used to estimate BWF contributions and define diurnal patterns (both weekday and weekend) within each flow monitor basin. DWF average values were generated for each flow monitor basin using average values obtained from the flow monitoring data.

The USEPA Sanitary Sewer Overflow Analysis and Planning (SSOAP) Toolbox was utilized to develop the DWF time patterns discussed in Section 5.5. The SSOAP Toolbox, in combination with Microsoft Excel, was used to adjust the parameters in order that the modeled DWF curve will match the observed data.

5.6.3 DRY-WEATHER FLOW CALIBRATION PROCESS

In general, the calibration process consisted of adjusting parameters in the model to make model simulations match observed data. The process of dry-weather model calibration was to adjust the GWI baseline values and baseline patterns to match the minimum observed flows. The DWF diurnal patterns were modified by adjusting, hourly, daily, and monthly factors, to match the magnitude, amplitude, and timing of the observed flow monitoring data. Adjustments were also made to Manning's roughness coefficient for conduits to help calibrate depth.

The calibration process was performed gradually from upstream subcatchments to downstream subcatchments. **Table 5.2** lists the flow monitoring locations and indicates which were not included due to poor quality data, by showing them in grey instead of black text.

²Data recorded in 2010 but used for model calibration

5.7 DRY-WEATHER FLOW CALIBRATION RESULTS AND DISCUSSIONS

The DWF model was calibrated to flow, depth, and volume for the periods shown in **Table 5.1**. Typical flow monitors record depth and velocity. Flow is a calculated value from the measured velocity and cross-sectional flow area (calculated from the measured depth). By calibrating to flow, depth, and volume (area under the flow curve) velocity is inherently calibrated as well. The Wastewater Planning Users Group (WaPUG) Code of Practice for The Hydraulic Modeling of Sewer Systems sets forth criteria for DWF calibration. A flow monitor area is considered to be well calibrated if the differences between simulated and observed maximum depth, peak flow, and total volume are within the range defined by the WaPUG criteria shown in **Table 5.3**. The difference in peak flow and total volume is calculated as the percentage of the observed peak flow and total volume, respectively. The difference in maximum depth is calculated in terms of depth.

Table 5.3: DWF WaPUG Calibration Criteria

Pipe Condition	Depth Criteria (ft)	Flow Criteria (%)	Volume Criteria (%)
Un-Surcharged	$-0.33 \leq \Delta \leq 0.33$	$-10 \leq \Delta \leq 10$	$-10 \leq \Delta \leq 10$
Surcharged	$-0.33 \leq \Delta \leq 1.67$	$-15 \leq \Delta \leq 25$	$-10 \leq \Delta \leq 20$

Figure 5.4 presents an example DWF calibration graph for flow monitor basin CSO-002E M052. The three graphs include the calibration of depth, velocity, flow, and flow volume. The graph shows the field measured data as a heavy black curve (M052 (obs)). The diurnal pattern is clearly evident in the observed data. The model generated flows are shown as a thin red curve (002-243_U and M052) on top of the observed data. Appendix G presents DWF calibration plots for all flow monitor basins. Overall, the

DWF calibration simulation results are within the range of WaPUG criteria for most of the flow monitor basins.

Figure 5.4: CSO-002E_M052 DWF Calibration Hydrograph¹

¹Friday July 8 recorded a spike in flow at this meter location;
This extraneous point was not considered when calibrating DWF

Figure 5.5 summarizes the DWF depth calibration for flow monitor basin CSO-002E_M052 using a scatter plot. Each data point represents the pairing of calibrated model and observed data. The data points located outside the range of “upper” and “lower” lines violate the WaPUG criteria for DWF. These data points are typically outside of the WaPUG criteria because of a data error or missing data. A data error may occur when the flow monitor sensor has a problem (e.g. debris on the sensor or the sensor reading drifts over time). Evidence of this is clearly recognizable when analyzing the data. Missing data occurs when a portion of the flow data for a given duration is missing or a constant value is recorded. **Figure 5.6** shows the DWF scatter graph for flow at flow monitor basin CSO-002E_M052. **Figure 5.7** summarized the DWF volume calibration for flow monitor basin CSO-002E_M052.

Figure 5.5: CSO-002E_M052 DWF Calibration Depth Scatter Plot

Figure 5.6: CSO-002E M052 DWF Calibration Flow Scatter Plot

Figure 5.7: CSO-002E M052 DWF Calibration Volume Scatter Plot

Table 5.4 summarizes the DWF model simulation for maximum depth, peak flow rate, and total flow volume at all flow monitor basins used for calibration. The average absolute difference in simulated and observed maximum depth is 0.02 feet. The average absolute difference in simulated peak flow and observed peak flow is 0.08 MGD. The average absolute difference of simulated volume and observed volume is 0.01 MG. Overall, model simulation results show good agreement with the observed flow and the differences are within acceptable ranges for collection system modeling.

5.8 DRY-WEATHER FLOW VERIFICATION

To verify the DWF calibration, the model was run to simulate the entire monitoring period. This DWF model was run without the simulation of precipitation to isolate the DWF only. The periods of DWF other than the period used for calibration were identified and analyzed to verify the DWF calibration. Minor adjustments to the baseline or monthly patterns were made as needed to complete the model DWF verification.

Table 5.4: DWF Depth and Flow Calibration Summary

5.9 DRY-WEATHER FLOW EXTRAPOLATION TO TYPICAL YEAR

In contrast to single-event calibrations that may simulate up to several days, a continuous calibration may simulate several months or years during which the DWF, especially the GWI, varies month-to-month and season-to-season. The flow monitoring period for the City of Lakewood was only several months and not several years; therefore, the GWI seasonal variation was not captured in the flow monitoring data.

The Lakewood typical year model was configured so that the GWI and diurnal parameters can be adjusted monthly. In the absence of field measured data, it was reasoned that the months without data would be supplemented with observed data. A method was developed to complete the typical year model with available data. A yearly calendar can be separated into two distinct seasons based on the growth and dormancy of the local vegetation. The growth season can be defined as the days between the last frost of the spring and the first frost of the autumn. Conversely, the dormant season is the period between the first frost of the autumn and the last frost of the spring. For Ohio, the growth season generally lasts from April through September and the dormant season is usually October through March.

Due to the period of flow monitoring performed for the Lakewood system model, most data were collected during the growth season. Some flow monitors were installed early enough in the season to capture flow data in April. If April data were collected and of good quality, these dormant season parameters were applied to dormant season months during which data were not collected. In the absence of good quality April data, May parameters were applied to the dormant season months without data. May, which can be classified as a “transition” month between dormant and growth season, exhibits characteristics much more similar to the dormant season than June, July, or August, the months during which flow monitoring data were collected.

Some flow monitors were removed from the system in early August and others were removed later in August. If August data were collected and of good quality, these growth season parameters were applied to September which did not have data collection. September, which can often be classified as a “transition month” between growth and dormant seasons, usually resembles growth season parameters much more closely than dormant season parameters. In the absence of good quality August data, July parameters were applied to the growth season months without data (August and September). **Table 5.5** presents the monthly parameters that were applied for each month in the typical year model.

Table 5.5: DWF Patterns Used for Typical Year Model

Month	Flow Monitor Data	Season	Data Used in Typical Year Model¹
January	No	Dormant	April/May
February	No	Dormant	April/May
March	No	Dormant	April/May
April	Yes/No ¹	Dormant/Transition	April/May
May	Yes	Growth/Transition	May
June	Yes	Growth	June
July	Yes	Growth	July
August	Yes/No ¹	Growth	July/August
September	No	Growth/Transition	July/August
October	No	Dormant	April/May
November	No	Dormant	April/May
December	No	Dormant	April/May

¹Some flow monitors had data and were calibrated for April or August; others did not have data and were not calibrated. The Typical Year model was completed by matching monthly parameters to Growth or Dormant seasons.

CHAPTER 6 – WET-WEATHER FLOW CALIBRATION

6.1 WET-WEATHER FLOWS

Wet-weather flow (WWF) in a sanitary or combined sewer collection system is the combination of domestic, commercial, and industrial wastewater flow with the addition of rainfall derived infiltration and inflow (RDII). **Figure 6.1** shows a visual representation of the WWF response to precipitation on top of normal dry-weather flow (DWF). Chapter 5 discusses the elements of DWF in detail.

Figure 6.1: Wet-Weather Flow Response

The magnitude of RDII flows are directly related to the intensity and duration of the precipitation, the relative soil moisture at the time of the precipitation event, the condition of the sewers, and the size of the tributary area among other factors. It is not uncommon for peak flows during precipitation events to be the highest flow rates that occur in the collection system.

Infiltration and inflow (I/I) is problematic in a sanitary sewer collection system because it eliminates valuable capacity from the system that is normally reserved for sanitary sewage flows. Every sewer system experiences some degree of I/I; however, excessive I/I creates system back-ups, sanitary sewer overflows (SSOs), and basement flooding problems (BFP). I/I enters the collection system through illicit direct connections (e.g. downspouts, catch basins, inlets) or defects in sewer pipes, manholes, or service laterals (e.g. cracks, fractures, defective joints).

The SWMM model has specific input parameters to replicate observed RDII and WWF. Most common in stormwater collection system models is the runoff method. The unit hydrograph method (commonly referenced as the RTK method) is the most common

method for generating WWF in sanitary sewer collection system models. Combined sewer models may use either the runoff method or the RTK method, or a combination of both methods. Each method for generating WWF in the SWMM model is discussed in the subsequent sections.

6.1.1 RUNOFF METHOD

To create a wet-weather response in the collection system, the SWMM model simulates precipitation on a catchment area. When the precipitation exceeds the infiltration parameters, the excess precipitation (runoff) is the influent to the collection system.

6.1.2 RTK METHOD

To create a wet-weather response in the collection system without modeling subcatchments, the SWMM model uses a combination of unit hydrographs to simulate a rapid, intermediate, and long response. The total response in the sewer is represented by the sum of the three responses. **Figure 6.2** shows the three unit hydrographs and the total system response. The unit hydrographs are represented by three parameters:

- R: The percent of precipitation that enters the sewer system
- T: The time to peak of the unit hydrograph
- K: The ratio of the time to peak to the recession limb of the unit hydrograph

Figure 6.2: Total, Rapid, Intermediate, and Long RTK Response

6.2 WET-WEATHER EVENTS

A variety of sources may be utilized to determine wet-weather events for the model. Data are typically available from sources such as:

- National Oceanic and Atmospheric Administration (NOAA)

- National Weather Service (NWS)
- State Climate Offices
- Synthetic Precipitation Events
- Community Rain Networks
- Radar Rainfall
- Rain Gauge Monitoring

Synthetic precipitation events are traditionally used for predictive purposes after the model is calibrated. Projections of how the collection system will behave under a set of conditions (or proposed improvements) are often the end-goal of a modeling effort. The model can be used to predict the volume and frequency of overflows, flooding manholes, or potential BFPs.

Just as actual flow monitoring data is used to calibrate the model, actual precipitation gauge measurements should be used for calibration purposes. Actual precipitation records may come as long-term time series from sources such as NOAA and the NWS or records may be of a shorter temporal horizon from instruments installed specifically for the purposes of the modeling project. For calibration efforts, it is desirable to obtain precipitation records on the order of 5-minute to 10-minute resolution. One-hour resolution can be used for modeling exercises such as running a typical year simulation, but should not be used for detailed calibration. If hourly precipitation data is the only data available, it should be disaggregated into 5- to 10-minute resolution for detailed calibration.

Precipitation gauge site selection is also important to capturing wet-weather events. Poor precipitation data will adversely affect flow monitor calibration. While not always practical or affordable, radar rainfall typically provides the highest degree of spatial resolution. Precipitation gauges should be installed to adequately cover the study area. A minimum of three precipitation gauges are required and where possible, the gauges should be placed such that obstructions are an acceptable distance from the gauge (typically the acceptable distance from a gauge to an obstruction is the height of the obstruction). Wet-weather events can be identified from the time series recorded by each precipitation gauge.

6.2.1 WET-WEATHER EVENT IDENTIFICATION

In general, monitoring equipment (flow monitors and precipitation gauges) data should capture at least three acceptable precipitation events and system responses. Precipitation for wet-weather events should be:

- Large enough to generate runoff from the entire subcatchment
- Greater than 0.2 inches in depth
- Minimum 0.25 inches per hour in peak intensity
- Temporally independent (sufficient time for the flow to return to DWF between events)

Wet-weather events should produce peak flows such that:

- The response is large enough to negate any inherent measurement errors
- Flow responses are at least 1.5 to two times average DWF
- The flow depth exceeds 0.33 feet
- The flow velocity exceeds twice the DWF velocity and at least 0.66 feet per second

6.2.2 WET-WEATHER EVENT ANALYSIS

Precipitation data were collected for the Lakewood system model from May 5, 2011 through August 5, 2011. The data were collected on 10-minute intervals at the locations shown in **Figure 4.1**. Precipitation gauges were located at Lincoln Elementary School, Fire Station No. 1, and City Hall. Precipitation data from the wastewater treatment plant (WWTP) was not used for calibrating. The rain data from the other three rain gauges represent a more accurate representation of the rainfall data across the monitoring area.

Data from each gauge were analyzed for precipitation events. Experience determined that a four hour period between events would most likely satisfy temporal independence criteria. **Table 6.1** shows the precipitation statistics for the identified events.

Table 6.1: Identified Precipitation Events¹

Event #	Start Date	Duration (HH:MM)	Total (in)	Recurrence Interval	Peak (in/hr)	Recurrence Interval
1	5/14/2011	57.00	1.28	2-mo 72-hr	0.33	<2-mo 1-hr
2	5/25/2011	12.25	1.55	9-mo 12-hr	1.12	2-yr 1-hr
3	5/29/2011	0.50	0.56	6-mo 30-min	0.56	2-mo 1-hr
4	6/7/2011	0.94	0.62	3-mo 1-hr	0.62	3-mo 1-hr
5	6/19/2011	6.72	1.03	4-mo 6-hr	0.88	6-mo 1-hr
6	7/19/2011	7.44	3.86	50-yr 6-hr	1.92	25-yr 1-hr
7	7/22/2011	2.78	0.97	6-mo 3-hr	0.94	1-yr 1-hr
8	7/23/2011	5.28	0.70	<2-mo 6-hr	0.34	<2-mo 1-hr

¹The average precipitation from Lincoln_RG, CityHall_RG, and FireStation1_RG was used to determine acceptable calibration events. Meters were calibrated to precipitation from an individual gauge, not the average values shown in Table 6.1.

Not all flow monitors collected good quality data for all the identified precipitation events shown in **Table 6.1**. Data from each flow monitor were examined independently and each flow monitor was calibrated to at least three events. Most flow monitors were calibrated to as many precipitation events as possible.

6.3 INITIAL PARAMETERS

The calibrated DWF model was used as the starting point for the WWF model. The initial parameters in the WWF model were the DWF time series for monthly, daily, and hourly variations used to create the observed diurnal patterns.

The raw flow and precipitation data were analyzed in the USEPA's Sanitary Sewer Overflow Analysis and Planning (SSOAP) Toolbox to generate unit hydrograph parameters; R, T, and K. The WWF calibration process is described in Section 6.4.

6.4 CALIBRATION AND VERIFICATION PROCESS

In general, the calibration process consists of adjusting the non-measurable parameters in the model to match model simulations to flow monitor observations. Before the calibration process, the observed data were reviewed and only the acceptable data were selected for calibration. The calibration process was performed gradually from upstream flow monitor areas to downstream areas.

The model was considered calibrated if the simulated peak water depth, peak flow, and total flow volume satisfied the WaPUG criteria shown in **Table 5.3**.

6.4.1 SSOAP CALIBRATION

The approach used to characterize the WWF response is known as the unit hydrograph method. The unit hydrograph parameters (RTK) were generated for each flow monitor area. A total of 224 monitor-storms were analyzed, each representing one storm event at one of the 28 flow monitoring sites utilized for calibration. Although there were 53 flow monitoring sites (50 in 2011 and three from 2010) and eight events analyzed, reliable flow monitoring data or precipitation data was not available for all flow monitors for every storm event. The RTK parameters for each flow monitor for each event are summarized in Appendix H of this report.

6.4.2 SWMM CALIBRATION

Using the DWF calibrated model, the WWF calibration process started with the addition of the RTK values obtained from the RDII analysis for each calibration event using the SSOAP Toolbox. The RTK values were then adjusted to match the observed peak flow, total event volume, and peak flow timing. Lastly, Manning's n and sediment depth were adjusted to calibrate velocity and water level. The results of the calibration effort are discussed in detail in Section 6.5.

6.5 CALIBRATION AND VERIFICATION RESULTS

The WWF model was calibrated at 28 flow monitor locations for at least eight storm events:

- May 14, 2011
- May 25, 2011
- May 29, 2011
- June 7, 2011

- June 19, 2011
- July 19, 2011
- July 22, 2011
- July 23, 2011

Table 6.2 lists the flow monitor name, the manhole where the monitor was installed, and the conduit where the meter was installed, which had reliable data used in the model. The flow monitors listed in **Table 5.3** were used for model calibration. Other flow monitors did not record quality data and were not used for model calibration. **Figure 6.3** shows the flow monitor locations from **Table 6.2** and **Figure 6.4** shows the locations of the nine permitted CSOs.

For each of the nine CSO areas, the model calibration is summarized by flow monitor using scatter plots of simulated versus observed peak depth, peak flow, and total flow volume. The calibration points located outside the range of “upper” and “lower” lines violate the WaPUG criteria and are classified into three groups of errors:

- Data error
- Missing data
- Modeled error

A data error may occur when the flow meter sensor has problem such as debris on the sensor, the sensor is shifted, etc. Missing data is defined as a partial or whole period of the storm event with no flow data or the flow data was assigned to a constant value. A modeled error is defined as the model over or under predicting the water level or flow during an individual calibration event, but well-calibrated for the other storm events.

\\mtr-fs1\mtr-vol1\2011\1101601\REPORTS\Ch-6\Figure 6-05 Overflow Locations.mxd

6.5.1 CSO-002

Overflow CSO-002 is located just upstream of the head-works of the WWTP. When WWF exceeds the plant capacity, CSO-002 is utilized as a bypass. CSO-002 discharges to the WWTP outfall tunnel that discharges to Lake Erie. **Figure 6.5** is a detail of the influent head chamber just upstream of the WWTP headworks. The overflow is indicated on the figure. While the City has a permanent flow monitor installed to record the activation of CSO-002, a temporary flow meter was not installed at this location for the purposes of this project due to safety concerns for accessing and installing a meter on the City's interceptor sewer. At this location, the interceptor sewer is approximately 70 feet beneath the street surface. Data from the CSO-002 meter was used to calibrate CSO activations, but due to limitations with the available data, the data could not be used to calibrate to particular precipitation events.

HEAD CHAMBER

6.5.2 CSO-002A

Sanitary sewer flow from the CSO-002A area was monitored at Sloane and West Clifton. The flow heads north to the interceptor on West Clifton near the railroad tracks. An overflow to the storm sewer is located where the sanitary sewer connects to the interceptor. This storm sewer discharges to the Rocky River.

Figure 6.6 shows the WWF depth calibration plot for flow monitor M044.

Figure 6.7 shows the WWF flow calibration plot for M044 and **Figure 6.8** shows the WWF total volume calibration plot for M044.

Figure 6.6: M044 WWF Depth Calibration Plot

6.5.3 CSO-002B

Sanitary sewer flow from the CSO-002B area was monitored at the southwest corner of Clifton and West Clifton. An overflow to the storm sewer is located just south of where the sanitary sewer connects to the interceptor. This storm sewer discharges to the Rocky River. **Figure 6.9** shows the WWF depth calibration plot for flow monitor M045. **Figure 6.10** shows the WWF flow calibration plot for M045 and **Figure 6.11** shows the WWF total volume calibration plot for M045.

Figure 6.11: M045 WWF Volume Calibration Plot

6.5.4 CSO-002C

Sanitary sewer flow from the CSO-002C area was monitored at Detroit and West Clifton. Several overflows exist throughout the CSO-002C area. These overflows discharge to the storm sewer on West Clifton which discharges to the Rocky

River. **Figure 6.12** shows the WWF depth calibration plot for flow monitor M043. **Figure 6.13** shows the WWF flow calibration plot for M043 and **Figure 6.14** shows the WWF total volume calibration plot for M043.

Figure 6.12: M043 WWF Depth Calibration Plot

Figure 6.13: M043 WWF Flow Calibration Plot

Figure 6.14: M043 WWF Volume Calibration Plot

6.5.5 CSO-002D

Sanitary sewer flow from the CSO-002D area was monitored at southeast corner of the intersection of Webb and Clifton. Several overflows exist throughout the CSO-002D area. These overflows discharge to the storm sewer on Webb Road which discharges to Lake Erie. **Figure 6.15** shows the WWF depth calibration plot for flow monitor M047. **Figure 6.16** shows the WWF flow calibration plot for M047 and **Figure 6.17** shows the WWF total volume calibration plot for M047.

Figure 6.15: M047 WWF Depth Calibration Plot

Figure 6.16: M047 WWF Flow Calibration Plot

Figure 6.17: M047 WWF Volume Calibration Plot

6.5.6 CSO-002E

Overflow CSO-002E is located at Summit and Edgewater and discharges to Lake Erie. **Figure 6.18** shows the WWF depth calibration plot for flow monitor M052. **Figure 6.19** shows the WWF flow calibration plot for M052 and **Figure 6.20** shows the WWF total volume calibration plot for M052.

Figure 6.18: M052 WWF Depth Calibration Plot

Figure 6.19: M052 WWF Flow Calibration Plot

Figure 6.20: M052 WWF Volume Calibration Plot

6.5.7 CSO-002F

Sanitary sewer flow from the CSO-002F area was monitored on Riverside between Crest and Franklin and contribute to the flow at the CSO 002 overflow which discharges to Lake Erie via the WWTP outfall tunnel. **Figure 6.21** shows the WWF depth calibration plot for flow monitor M042. **Figure 6.22** shows the WWF flow calibration plot for M042 and **Figure 6.23** shows the WWF total volume calibration plot for M042.

Figure 6.21: M042 WWF Depth Calibration Plot

Figure 6.22: M042 WWF Flow Calibration Plot

Figure 6.23: M042 WWF Volume Calibration Plot

6.5.8 CSO-052

Overflow CSO-052 is located at the west end of Madison at the intersection of Madison and Riverside. The reported overflows are currently being monitored on a stormwater pipe upstream of the actual overflow structure. It is expected that CSO-052 does not activate as often or discharge as much sanitary sewage volume as is being reported. Since the monitor is on the storm sewer side of the overflow, CSO activation is being reported when the storm sewer starts to flow, not when the sewer overflows the CSO structure. CSO-052 discharges to the Rocky River. **Figure 6.24** shows the WWF depth calibration plot for flow monitors M004, M006, M007, M008, and M014. **Figure 6.25** shows the WWF flow calibration plot for M004, M006, M007, M008, and M014 and **Figure 6.26** shows the WWF total volume calibration plot for M004, M006, M007, M008, and M014.

Figure 6.26: M004, M006, M007, M008, and M014 WWF Volume Calibration Plot

6.5.9 CSO-053/054

Overflow CSO-053 is located at the western edge of the WWTP on Valley Parkway. CSO-054 is located on Detroit Avenue Extension. Both discharge to the Rocky River. Part of the tributary area for CSO-053 is monitored by flow monitor M114 at Detroit and Scenic. The accuracy of the CSO-053 overflow is influenced by the flow from residences in the City of Rocky River that are serviced by the Lakewood WWTP. This flow was not modeled. **Figure 6.27** shows the WWF depth calibration plot for flow monitor M114. **Figure 6.28** shows the WWF flow calibration plot for M114 and **Figure 6.29** shows the WWF total volume calibration plot for M114.

Figure 6.27: M114 WWF Depth Calibration Plot

Figure 6.28: M114 WWF Flow Calibration Plot

Figure 6.29: M114 WWF Volume Calibration Plot

6.5.10 CSO-055

Overflow CSO-055 is located at the intersection of Edgewater and Kenneth. CSO-055 discharges to Lake Erie. **Figure 6.30** shows the WWF depth calibration plot for flow monitor M015. **Figure 6.31** shows the WWF flow calibration plot for M015 and **Figure 6.32** shows the WWF total volume calibration plot for M015.

Figure 6.30: M015 WWF Depth Calibration Plot

Figure 6.31: M015 WWF Flow Calibration Plot

Figure 6.32: M015 WWF Volume Calibration Plot

6.5.11 CSO-056

Overflow CSO-056 is located at the intersection of Rosalie and Edgewater. The overflow is actually two separate pipes; however, they are monitored together and reported as a single overflow. It is expected that CSO-056 does not activate as often or discharge as much sanitary sewage volume as being reported. This is because the overflow is also the storm sewer discharge for all of the CSO-056 area meaning that it will activate during rain events that may not cause an overflow upstream. CSO-056 discharges to Lake Erie. **Figure 6.33** shows the WWF depth calibration plot for flow monitors M016, M018, M051, and M070. **Figure 6.34** shows the WWF flow calibration plot for M016, M018, M051, and M070 and **Figure 6.35** shows the WWF total volume calibration plot for M016, M018, M051, and M070.

CHAPTER 7 – INTERCEPTOR SEWER VERIFICATION

7.1 INTRODUCTION

The City of Lakewood's (City) interceptor sewer was constructed from 1920 to 1940 to provide relief for overloaded local collection system. The sewer was constructed in two phases, first, from the wastewater treatment plant (WWTP) to Nicholson Avenue in 1920 and, second, from Nicholson Avenue to West 117th Street in 1930. The interceptor sewer was constructed as a segmental block tile sewer in a City of Cleveland Standard Egg shape. Most of the interceptor sewer is a No. 7 egg with dimensions shown in **Figure 7.1**.

Figure 7.1: Dimensions of Standard No. 7 Cleveland Egg Sewer

The City's interceptor begins (in the direction of flow) at the northeast corner of the City at W. 117th St. and Edgewater Dr. and generally follows the alignment of Edgewater Dr. west parallel to Lake Erie. The interceptor follows Webb Road south towards Clifton Blvd., turns west on Clifton Blvd., and then south again on W. Clifton Blvd. It follows W. Clifton Blvd. south to the Rocky River where it crosses the river via an aerial sewer to the City's WWTP. The interceptor sewer is 100 ft deep at its deepest location and 20 ft deep at its shallowest location. On average, the interceptor is approximately 60 ft deep. **Figure 7.2** shows the interceptor sewer route. Local sewers flow into the interceptor at numerous locations. **Figure 7.3** shows the interceptor profile from the City's SWMM model.

\\mtr-fs1\mtr-vol1\2011\1101601\REPORTS\Ch-7\Figure 7-XX Lakewood Interceptor.mxd

Figure 7.3: Interceptor Sewer Profile (flow from right to left)

7.2 FLOW MONITORING ON THE INTERCEPTOR

To develop the City's most comprehensive model to-date, it was desirable to install flow monitoring equipment on the interceptor sewer. Several locations were identified as potential locations for flow monitor installation; however, due to safety concerns for crew personnel installing the flow monitors, the interceptor was not monitored directly. Safety concerns include the depth of the interceptor sewer, high velocity in the interceptor sewer, and high volumes of traffic on a number of the streets above the interceptor.

The City maintains permanent CSO flow monitors along the interceptor which are used to report volume and frequency of the overflows. The CSO activations reported by the permanent flow monitors were used to calibrate CSO activations in the continuous simulation model. Chapter 8 of this report explains the continuous simulation model.

7.3 SEWER INSPECTION ON THE INTERCEPTOR

In April of 2011, the City contracted to have the interceptor sewer televised from the WWTP to W. 117th St. The data from this effort is presented in detail in Appendix I of this report for reference. Crews used closed circuit television (CCTV) and National Association of Sewer Service Companies (NASSCO) Pipeline Assessment and Certification Program ® (PACP) coding to record the condition of the interceptor sewer.

The information gathered from the CCTV effort was used to help calibrate the model at flow monitors adjacent to the interceptor sewer. Due to large amounts of accumulated debris, the model represented the No. 7 Egg sewer as a No. 5 Egg sewer on occasion. Select locations are shown in **Figures 7.4** through **7.8** to represent the condition of the interceptor sewer. **Figure 7.4** is the farthest upstream and **Figure 7.8** is the farthest downstream in the interceptor. As a result of the CCTV emergency repairs were performed on the interceptor between Lakeland Avenue and Summit Avenue.

Figure 7.4: Interceptor Sewer along Edgewater between Cove and Gold Coast

Figure 7.5: Interceptor Sewer along Edgewater between Lakeland and Summit

Figure 7.6: Interceptor Sewer along Clifton between Webb and West Clifton

Figure 7.7: Interceptor Sewer along West Clifton between Sloane and Detroit

7.4 SUMMARY

The overflows at CSO-002 and CSO-059 are both directly on the interceptor. The number of activations and volume of flow from the overflow monitoring data provided by the City was used to verify the modeled interceptor flow.

CHAPTER 8 – CONTINUOUS COLLECTION SYSTEM MODEL VERIFICATION

8.1 COMPREHENSIVE SWMM MODEL

The City of Lakewood (City) has nine permitted sewer overflows shown in **Figure 6.5**. To decrease simulation run times during calibration and facilitate data management, the City's collection system was modeled by unique overflow area. The CSO-002 and CSO-059 areas were subdivided because additional locations of potential overflow were identified. Sub-dividing CSO-002 and CSO-059 into smaller areas allowed the model to be created in greater detail upstream of potential overflows. CSO-053 and CSO-054 areas were combined into a single model because one could not be modeled without the other. Dry-weather flow (DWF) calibration and single-event wet-weather flow (WWF) calibration were performed on 15 individual models. Hydraulically independent areas were calibrated first and the calibration effort progress downstream until the entire City was calibrated. If an upstream model discharged to a downstream model, the results from the calibrated upstream model were used as input boundary conditions for the downstream model.

The 15 individual Lakewood models created for single-event calibration were an efficient method for model calibration, allowing the calibration effort to be completed simultaneously for several flow monitors. However, to assess the system's reaction under the influence of precipitation events, it was required to assemble the separate models into a single, comprehensive, system-wide model. Section 8.1.1 describes the general process of combining the individual models into a comprehensive city-wide model. Subsequent sections provide details as to how the assembly was performed.

8.1.1 COMPREHENSIVE MODEL ASSEMBLY

System-wide models are often developed as several smaller models that are easier to manipulate and shorter to run for calibration efforts. To perform a complete system analysis it is important to combine these smaller models into a large comprehensive model that encompasses the entire system. To assemble individual models into a single, comprehensive model, several steps are required. The general outline is:

1. Ensure duplicate names do not exist
2. Confirm separate models were developed using the same plane coordinate system
3. Create a new SWMM input file
4. Import modeling objects (e.g. junctions, outfalls, conduits, rain gages) from individual models to the new model
5. Resolve common objects between individual models

Individual models, previously calibrated, retain their calibration when merged into a single larger model as long as the input parameters remain the same. If a

downstream model was calibrated without the input from a calibrated upstream model, the downstream model would not be calibrated when assembled into a comprehensive model.

8.1.2 DUPLICATE NAME RECONCILIATION

When models are created independently, it is common that objects in each model have the same name even though they represent different physical entities in the collection system. For instance, a manhole in one model may be labeled as MH01 and located at the intersection of Main Street and High Street, while MH01 in a second model may be located at the intersection of High Street and State Street. If it is important to keep both MH01's in a combined model, the names must be changed to avoid duplicate names in the final model.

The naming convention developed for the City's collection system model followed a simple nomenclature that was descriptive and avoided confusion. The naming convention developed for the City's system-wide model makes the data easily readable and transferable to other models or other persons that may use the comprehensive model as reference for future projects. To avoid duplicate object names in the City-wide model, the nomenclature for naming nodes included a prefix of the overflow area, a letter designation of the specific collection system that contains the node, and the manhole number from the original model. Examples of sanitary, storm, and combined collection system nodes are as follows:

- Sanitary sewer junctions: **002S053** where "002" is the overflow area where the junction is located, "S" designates the Sanitary sewer, and "053" is a three-digit node identification number.
- Storm sewer junctions: **002T053** where "002" is the overflow area where the junction is located, "T" designates the sTorm sewer, and "053" is a three-digit node identification number.
- Combined sewer junctions: **052C104** where "052" is the overflow area where the junction is located, "C" designates the Combined sewer, and "104" is a three-digit node identification number.

The following nomenclature was used for naming subcatchments in the comprehensive, system-wide model: **S002T053**

- Prefix: To set the subcatchments apart from the nodes, the prefix "S" was used.
- Name: The basic name assigned to the subcatchments was the outlet node name. By changing the node names first, the outlet node in the subcatchments layer automatically updated.
- Optional Suffix: Occasionally two subcatchments were intentionally loaded to the same node. Because two subcatchments cannot be named identically, the second subcatchment was assigned the suffix "A." If necessary, subsequent nodes loaded to the same node will continue with the suffix "B," "C," etc.

The following nomenclature will be used for naming links in the comprehensive, system-wide model: **052S005_052T004**

- Upstream Junction ID: 052S005 where “052” is the overflow area where the junction is located, “S” designates the Sanitary sewer, and “005” is a three-digit node identification number.
- Underscore: _ this character is used to designate the end of the upstream node name and the start of the downstream node name.
- Downstream Junction ID: 052T004 where “052” is the overflow area where the junction is located, “T” designates the sTorm sewer, and “004” is a three-digit node identification number.

Using this convention supplies the user with ample information regarding the asset. First, since the junctions were named by “flow meter area, special character, and structure number,” the user can tell which flow meter area the pipe is located in. Also, the user can tell if the link is a sanitary, storm, or combined sewer. Lastly, from the downstream junction ID, the user can tell if the pipe spans two meter areas (i.e. it is the location of a flow meter) or if it spans two systems (e.g. an overflow pipe that goes from a sanitary sewer manhole to a storm sewer manhole).

8.1.3 IMPORT OBJECTS

PCSWMM can be used to import data directly from another SWMM input file. This feature allows the user to easily combine models into a comprehensive model. **Figure 8.1** shows the interface to import a SWMM input file. By using the check boxes provided the user can import specific portions of a model or the entire input file. Imported entities can be tagged with the original model name (or any other alpha-numeric character string) for easy reference to the original model from which the entities were imported.

8.1.4 COMMON OBJECT ELIMINATION

When individual models are imported into a comprehensive model, it is inevitable that some objects may be represented twice, even with the precautions taken in the previous steps to avoid duplicate names. Common objects in the comprehensive model are most often found at interface points between two of the individual models. The upstream model likely modeled a manhole as the “system” outfall and the downstream model modeled the same manhole as a node. Following the naming convention outlined in Section 8.1.2, both objects may be imported to the comprehensive model (with distinct names) and aligned directly on top of one another. To remove common objects, the conduit was directed to the node from the downstream model and the outfall from the upstream model was eliminated.

Figure 8.1: PCSWMM Import Interface for SWMM Input Files

8.2 LONG-TERM CONTINUOUS SIMULATION

Single-event models capture specific, isolated snapshots of a system’s response to precipitation. Long-term continuous simulation models are used to simulate complex hydraulic and hydrologic processes not found in single-event simulations. Continuous simulation models are frequently developed and used to simulate how the collection system responds to precipitation events under various antecedent moisture conditions, groundwater levels, and seasonal influences. A calibrated continuous simulation model can be used to predict the impacts of possible improvement scenarios and help select the most economical combination of improvement technologies to achieve the desired long-term goals. Many municipalities use dynamic long-term models to demonstrate how specific control measures will improve their integrated wet-weather improvement plan (IWWIP), limiting the frequency and volume of CSO or SSO events.

A long-term simulation model was used to predict how the system would respond to a “typical” year rainfall. This baseline can then be used to predict the average system overflow volume and frequency under future improvement conditions.

8.2.1 CONTINUOUS DRY-WEATHER FLOW

Long-term or continuous models may simulate several months or years during which the DWF, especially the GWI, varies month-to-month and season-to-season. The flow monitoring period for the City was completed over several

months that showed GWI fluctuations, but did not capture discernable seasonal variations.

The Lakewood continuous simulation model was configured so that the DWF parameters can be adjusted monthly. Since data was not collected for every month of the year, a method was developed to complete the typical year model with available data. By separating the year into two distinct seasons of growth and dormancy, the collected data was used to complete the model for months where data was not collected.

Most data for the Lakewood comprehensive system model were collected during the growth season. Some flow monitors were installed early enough in the season to capture flow data in April which can be considered a “transition” month if the data do not fit growth or dormant season trends. If good quality data were collected in April, the April parameters were applied to dormant season months during which data were not collected. In the absence of good quality April data, May parameters were applied to the dormant season months without data. May exhibits characteristics much more similar to the dormant season than June, July, or August, the months during which flow monitoring data were collected. A detailed explanation of the extrapolation of DWF parameters to the entire year can be found in Chapter 5 of this report.

8.2.2 CONTINUOUS WET-WEATHER FLOW

In contrast to single-event WWF models that simulate an isolated event over several hours up to several days, a continuous simulation model may simulate several months or years during which the WWF varies storm-to-storm, month-to-month, and season-to-season. During a continuous WWF simulation, the model responds to isolated storm events as well as back-to-back precipitation events. Wet-weather flow response is dependent on the precipitation characteristics and antecedent moisture conditions. During single-event calibration, a variety of storms and antecedent moisture conditions were selected to calibrate the model to system responses for multiple precipitation characteristics. The robustness created in the model from calibrating to a variety of single-events lends itself to continuous simulation scenarios.

Unit hydrograph R, T, and K parameters were fitted to the observed data using the United States Environmental Protection Agency (USEPA) Sanitary Sewer Overflow Analysis and Planning (SSOAP) toolbox. Most data for were collected during the growth season which typically exhibits short, intense precipitation events with significant amounts of runoff. Some flow monitors were installed early enough in the season to capture flow data in April which can be considered a “transition” month if the data do not fit growth or dormant season trends. Compared to the growth season, April precipitation events are generally lower in intensity and longer in duration, resulting in lower peak runoff rates and higher amounts of infiltration. If good quality data were collected in April, the April

RTK parameters were applied to dormant season months during which data were not collected. In the absence of good quality April data, May RTK parameters were applied to the dormant season months without data. May exhibits sewer response characteristics much more similar to the dormant season than June, July, or August, the months during which majority of the flow monitoring data were collected. Wet-weather parameters extrapolated to the entire year follow the same monthly criteria used during DWF extrapolation.

8.3 CONTINUOUS SIMULATION PRECIPITATION

8.3.1 2011 PRECIPITATION

The City's comprehensive model was used to establish a baseline for overflow events during May, June, July, and August of 2011. Data from the installed rain gauges were used to simulate the continuous model. Unlike the single-event calibrations presented in Chapter 6 of this report, the continuous model was used to simulate the system response over the three to four month period without any breaks. Running the simulation for the entire 2011 period accounts for back-to-back precipitation events where the soil does not have a chance to recover its full potential of infiltration and the system may not have returned to DWF conditions.

8.3.2 TYPICAL YEAR PRECIPITATION

The City's comprehensive model was used to establish a baseline for overflow events during a typical precipitation year. It is the baseline predictions from the model that will be used to determine system improvements in accordance with the City's integrated wet-weather improvement plan.

Data from Cleveland Hopkins International Airport (CLE) were obtained for the 33-year period from 1973 to 2006. The following criteria were considered desirable for the typical year precipitation data:

- No storm events greater than a 1-year storm
- Include a 1-year 1-hour storm
- Include a 6-month 1-hour storm
- Include a 4-month 1-hour storm
- Include a 3-month 1-hour storm
- Have remaining storms less than a 3-month storm
- Close to average precipitation reported by United States Department of Agriculture (USDA)

The precipitation events from the 33-year record were classified and calendar year 1977 (35.48 inches, total) came closest to the previously stated criteria. This year of precipitation data was submitted to the USEPA for evaluation. The USEPA assessed the proposed precipitation record and requested that the total precipitation for the year be raised from 35.48 inches to 37.52 inches based on the

CLE data (1973 to 2006) being more recent than the USDA data (1951 to 1976) previously used. To incorporate the additional precipitation requested, the 1977 monthly precipitation was compared to the monthly averages of the CLE data. January, February, May, September, and October were below the monthly average of the CLE data. The additional precipitation (2.04 inches) of precipitation was distributed to the below average months as shown in **Table 8.1**. The additional storms brought the respective monthly averages closer to the monthly averages of the CLE data.

Table 8.1: Additional Precipitation Added to Typical Year at Request of USEPA

Date (mm/dd/yyyy)	Time (hh:mm)	Precipitation (in)
01/16/1977	12:00	0.31
02/08/1977	12:00	0.21
05/08/1977	12:00	0.28
05/12/1977	12:00	0.28
05/16/1977	12:00	0.27
09/06/1977	12:00	0.38
10/29/1977	12:00	0.31
Total		2.04

The hourly precipitation data was converted to 15-minute precipitation data. During the discretizing process fractions of precipitation were rounded instead of truncated, resulting in a total yearly precipitation of 38.52 inches instead of the anticipated 37.52 inches. The rounding error from disaggregating the hourly precipitation was subsequently corrected. **Table 8.2** provides a summary of the typical year precipitation. The entirety of typical year precipitation data are presented in Appendix J of this report.

Table 8.2: Typical Year Precipitation Summary¹

Yearly Total (in)	37.52
Maximum Day (in)	1.76
Date of Maximum	6/30/1977
Maximum Month (in)	4.77
Month of Maximum	June

¹After USEPA requested modifications

8.4 CONTINUOUS SIMULATION SYSTEM RESPONSE

Results from the continuous simulations were analyzed to determine the system response at critical points. The system was investigated at the WWTP inflow and overflow locations.

8.4.1 CONTINUOUS SIMULATION CALIBRATION

Since the single-event models do not account for seasonal variations and antecedent moisture conditions, adjustments were made to the calibrated single-event models to create a calibrated continuous simulation model. These continuous calibration adjustments did not adversely impact the single-event model calibration status. An example of the continuous simulation calibration is shown in **Figure 8.2** for CSO-052 M018 and the Fire Station rain gauge. Another continuous simulation calibration hydrograph is presented in **Figure 8.3** for CSO-059 M028 and the City Hall rain gauge. A final example hydrograph is shown in **Figure 8.4** for CSO-002B M045 and the Lincoln rain gauge.

Figure 8.2: Continuous Simulation Calibration Hydrograph for CSO-052 M018

Figure 8.4: Continuous Simulation Calibration Hydrograph for CSO-002B M045

8.4.2 MODELED 2011 WWTP INFLOWS

Figure 8.5 shows the model predicted flows at the WWTP for May, 2011 through August, 2011. The head-works of the WWTP and operational procedures were modeled to the best available information provided by plant operators.

Figure 8.5: Modeled 2011 Flows to WWTP

8.4.3 MODELED 2011 OVERFLOW FREQUENCY AND VOLUME

Figure 8.6 shows the model predicted overflow activations for May through August, 2011. Because the model was only run for a four-month period, to determine the yearly statistics the results were multiplied by a factor of three to determine a “representative” 12-month activation frequency and volume. **Table 8.3** presents the “representative” results.

Figure 8.6: Modeled 2011 Overflows

Table 8.3: Modeled 2011 CSO Frequency and Volume Summary¹

Overflow	Modeled Node	Conduit	Frequency (#/yr)	Volume (MG)
002	CSO002	002C002_CSO002	30	276
052 ²	052T004	052S005_052T004	144	7,832

¹Frequency and volume represent a 12-month period simulated by the model

²CSO-052 is modeled as the true overflow pipe, not the storm pipe the flow monitor was on during 2011

³CSO-056 is reported as one outfall, but is physically two pipes

8.5 CONTINUOUS SIMULATION SUMMARY

Overall, the model calibrated very well to the CSO activations documented by the City for the period of flow monitoring performed for this project (from May to August, 2011). The 2011 continuous calibration provided confidence in the typical year model simulations. The 2011 precipitation record had several storms that were larger than any storm in the typical year precipitation record. Each precipitation record stressed the model in different ways. The 2011 precipitation record stressed the system response the short-duration, high-intensity precipitation events. The typical year precipitation record stressed the system to long-duration, low-intensity, and often back-to-back precipitation events. **Figure 8.9** presents a summary of the CSO activations modeled for May through August of 2011. The modeled typical year CSO activations are presented in **Figure 8.10** (by month) and in **Figure 8.11** (entire year).

The City's flow monitor for CSO-052 was installed on a stormwater pipe during 2011. It has since been moved to the correct combined-to-storm sewer pipe, which is the true CSO. Model results for the 2011 CSO activation represent the storm sewer pipe to show a good calibration at CSO-052, even in the storm sewer system. The model results for the typical year represent the true CSO pipe, and during a typical year precipitation, the model predicts zero CSO activations at CSO-052.

1.0 INTRODUCTION

In 1994, the Northeast Ohio Regional Sewer District (District) completed a regional study of Combined Sewer Systems called the CSO Facilities Plan Phase I Study. This study recommended a more comprehensive and consolidated approach to CSO Control in the Westerly Service Area. As a result, the District initiated the Westerly District Combined Sewer Overflow Phase II Facilities Plan. The Collection System Model Development and Verification report is part of the Phase II work undertaken by the District.

Purpose

The Westerly District CSO Phase II Facilities Planning Study, and thus the modeling, involves the refinement of the findings from the Phase I Study. Specifically, the goal of the study was to develop a wet weather long term control plan (LTCP) for the Westerly District that minimizes the CSO impact on receiving waters, as required by Ohio EPA's CSO Policy. To accomplish these goals, the collection system was modeled in greater detail than the Phase I study.

Scope

This report outlines the development and verification of a detailed hydraulic model of the Westerly Service Area collection system. The model was developed as part of Task B – Facilities Planning. The Westerly CSO Phase II Facilities Planning Report contains modeling information about baseline assessment and alternatives analyses.

2.0 WESTERLY DISTRICT COLLECTION SYSTEM DESCRIPTION

The project area is shown in Figure 2-1. This area is located largely in the city of Cleveland and is about 10,000 acres. The District's interceptor system serving the Westerly Treatment Plant is shown on Figure 2-1, also. The four major interceptors include the Northwest, Westerly, Walworth Run, and Cuyahoga River (Low Level). A brief description of each of the interceptors follows the general description of the Westerly Service Area below.

2.1 Service Area Characteristics

The Westerly District service area is a predominantly urban catchment with a mixture of land uses. The catchment contains a large industrial section, well-maintained residential areas, and parkland. Sensitive bathing and recreation areas along Lake Erie, the Cuyahoga River, and Rocky River add a unique quality to this sewer service area.

The topography of the Westerly service area is predominantly flat with the only significant ground slopes found along the Lake's shore and the western boundary with Rocky River. However, the sewer system is drained by gravity with pumping stations only serving local low-lying neighborhoods and the flat areas along the Cuyahoga River.

The collection system contains both a combined and separate sewer area. The separate area lies in the Western portion of the service area and comprises about one-third of the drainage area. The combined sewers drain the remaining two-thirds of the catchment.

2.2 Northwest Interceptor

The Northwest Interceptor is comprised of two segments: (1) a upstream segment that conveys dry-weather flows from western portions of the sewershed to the Westerly Interceptor at the intersection of Lake Avenue and West 117th Street and (2) a downstream segment that conveys only wet-weather flow conveyance from near the W. 117th St. and Edgewater Ave. intersection to the Combined Sewer Overflow Treatment Facility (CSOTF).

This lower segment of the Northwest Interceptor, a 20-foot by 9-foot conduit, begins at the District's Combined Sewer Overflow Treatment Facility (CSOTF) located adjacent to the WWTP and proceeds west across lower and upper Edgewater State Park to Edgewater Drive and West Boulevard (pipe size 20' x 9'). The interceptor then proceeds west along Edgewater Drive to West 117th Street and then south along West 117th Street to a location just north of Lake Avenue (pipe size 120").

At West 117th and Detroit Road, the upper segment of the Northwest Interceptor is diverted to the Westerly Interceptor. Thus, all dry weather flow and a portion of the wet

weather flow from the upper portion of the Northwest Interceptor are conveyed to the Westerly Wastewater Treatment Plant through the Westerly Interceptor rather than the lower Northwest Interceptor.

The upper segment of the Northwest Interceptor begins at the vicinity of West 117th St., south of Lake Avenue (pipe size 30"). The interceptor then proceeds south along the east side of West 117th Street to Berea Road (pipe size 30" to 108"). Along Berea Road, the interceptor runs on the south side southwest to Lakewood Heights Boulevard (pipe size 108"). The interceptor then proceeds along Lakewood Heights Boulevard to Bunts Road, south along Bunts to Marginal Road (south of Interstate 90) and then west along Marginal Road to West 159th Street (pipe size 108"). The interceptor then proceeds south along West 159th Street to Fischer Road, west along Fischer Road to Rocky River Drive and south along Rocky River Drive to Puritas Avenue (pipe size 66" to 108").

2.3 Westerly Interceptor

Beginning at the Westerly Wastewater Treatment Plant, the Westerly Interceptor (pipe size No. 4) proceeds south along the line of West 58th to a point approximately 250 feet north of the intersection of Cass Avenue and West 58th Street. At that point, the interceptor (pipe size 6'-6") continues due west to the railroad tracks. The interceptor heads southwest down the railroad tracks to Lake Avenue (pipe size 3'-8'). At Lake Avenue and the railroad tracks, the interceptor goes northwest up Lake Avenue to West 117th Street (pipe size No. 8 to 8'-6").

At Lake Avenue and the railroad tracks, the Westerly Interceptor continues down Desmond Avenue to approximately West 98th Street (pipe size 9'-6") and then south to Detroit Road (pipe size 7'-9"). At Detroit and West 98th the interceptor (pipe size 6') moves west along Detroit to Berea Road. At Berea and Detroit the interceptor turns southwest down Berea Road to Lakewood Heights Boulevard (pipe size 30" to 5'-9"). Here the interceptor turns west down Lakewood Heights Boulevard and continues to Warren Road (pipe size 24"-5').

2.4 Walworth Run

Main Branch

The Walworth Run Interceptor begins at the Westerly Wastewater Treatment Plant and generally follows the West Shoreway to approximately West 33rd Street (pipe size 5'-6"). The interceptor moves down West 33rd Street to Franklin Boulevard (pipe size 5'-6"). At Franklin and West 33rd the interceptor cuts southeast to Woodbine Avenue and West 32nd St. (pipe size 5'-6"). Continuing southeast, the interceptor crosses Whitman Avenue and through the intersection of Fulton Road and Bridge Avenue (pipe size 5'-6"). From this intersection the interceptor moves down West 32nd to Monroe Avenue (pipe size 5'-6"). From this point the interceptor moves southeast to West 30th Street

and St. Louis Railroad, and then down West 30th to Trowbridge Avenue (pipe size 2'-6" to 10'-3"). Gaining Trowbridge Avenue the interceptor (pipe size 5'-6") moves down Trowbridge to West 25th Street and then down West 25th to Bradwell Avenue (pipe size 21" to 8'-9").

Clark Avenue Branch

From West 30th Street and the St. Louis Railroad, the Walworth run interceptor follows Walworth Run westward to West 55th Street and Walworth Avenue (pipe size No. 5 to 14'-9"). The interceptor then goes down Walworth Avenue to West 65th Street and Clark Avenue (pipe size 8' to 9'-6"). The interceptor then goes west following Clark Avenue to Lorain Avenue (pipe size No. 6 to 6'-6").

Tremont Branch

Beginning at West 30th Street and the St. Louis Railroad the interceptor moves east gaining and following Walworth Avenue to Brevier Avenue (pipe size No. 4 to No. 5). The interceptor goes down Brevier Avenue to Shay Court and then along Kenilworth Avenue, crossing Scranton Avenue, to West 14th Street (pipe size No. 4 to 5'). The interceptor goes up West 14th to the area of University Road, then crosses to Railway Avenue. The interceptor follows Railway Avenue to West 10th Street (pipe size 5').

2.5 Cuyahoga River (Low Level)

Parting from the Walworth Run Interceptor at West 33rd St. and Detroit Avenue, the Cuyahoga River interceptor heads east along Detroit to approximately West 31st Street (pipe size No. 7). Here it turns northeast to West 29th St. and Vermont Avenue and then up West 29th to the Sewage Pumping Station at Division Avenue and West 29th St. (pipe size No. 7). From the pumping station, the interceptor (pipe size 36") follows River Road to Elm Street. From this intersection the interceptor moves down Elm to the Main Street Bridge level and follows the Main Street bridge until it passes Sycamore Street (pipe size 36"). Bisecting the area between Riverbed Street and Sycamore Street the interceptor crosses Winslow Street and moves to Washington Street (pipe size 36"). Upon reaching Washington Street the interceptor heads towards the river to Riverbed Street (pipe size 36"). At Cathan Avenue the line crosses to Detroit Avenue at the Sycamore level. Gaining Detroit Avenue the interceptor follows Detroit, crossing under the Detroit-Superior Bridge and gains Riverbed Avenue (pipe size 36"). The interceptor follows Riverbed Avenue and at Columbus Road follows Carter Road to Scranton Road (pipe size 24" to 5'). From this intersection the interceptor proceeds down Scranton Road to University Road and then down University Road to the area of the Inner Belt Freeway (pipe size 24" to 5').

3.0 COLLECTION SYSTEM MONITORING PROGRAM

The Westerly District Flow and Rainfall Monitoring Program was conducted from April through mid-August, 1997. ADS Environmental Services performed the actual monitoring for the program, while Metcalf and Eddy and Montgomery Watson provided coordination and technical assistance for site selection, meter calibration, and data quality assurance and control. Further description of the flow and rainfall monitoring program is presented in the Sewer System Evaluation Survey Report, dated July 1998.

A total of 106 flow monitors and 7 rain gauges were installed to collect data about the flows in the sewer system and rainfall event information. Figure 3-1 presents the graphical locations of the flow monitors and rain gauges installed for this study. (This large figure can be found folded and placed in the map pocket at the end of this document.) Table 3-1 lists the street locations of flow monitors and rain gauges. Table 3-2 summarizes the rainfall events recorded during the flow monitoring period.

Figure 3-2 shows the coverage of each rain gauge in the Westerly Service Area. The rain gauge coverages were determined using Thiessen's polygon method. The Thiessen polygon method determines the area representation of a rain gauge in a rain gauge network. Thus, for modeling purposes, all sewer-sheds in a rain gauge polygon receive the rainfall recorded at that gauge.

Table 3-1: Flow Meter and Rain Gauge Locations

Flow meter	Location	Description
3054R-I	West 25th Street and Columbus Avenue	Regulator inlet
3056R-I	1719 Willey Avenue	Regulator inlet
3070R-D	West 30th Street and Barber Avenue	Regulator dry weather outlet
3070R-I	West 30th Street and Barber Avenue	Regulator inlet
3090R-D	Train Avenue and Barber Avenue	Regulator dry weather outlet
3090R-I	Train Avenue and Barber Avenue	Regulator inlet
WR10-O	near Sycamore Street and Main Street intersection	Cuyahoga River inflow analysis (water depth only)
CSO-1	3780 Rocky River Drive behind Kamms Plaza	Mixed
CSO-2	Beltline at Jennings Road; Dennison Road bridge north of railroad tracks	Mixed
CSO-3	East of Quigley Road at Cuyahoga River (I-490 drainage)	Mixed
CSO-4	Columbus Road and Riverhead (east of bridge north of Carter Road)	CSO
CSOTF	Westerly Wastewater Treatment Plant - CSO outfall conduit	At CSO treatment facility
Lakewood	Lake Avenue and West 117th Street intersection	Regulator dry weather outlet
LL-1	University Road, east of Scranton Road	Regulator inlet
LL-2	2065 Scranton Road	Regulator dry weather outlet
LL-3	Low Level Interceptor along Riverbed Road, west of Columbus Road	Interceptor
LL-4	1200 Division Avenue	Pump station interceptor
NW1D2D	East of Desmond Avenue & Lake Avenue intersection along railroad tracks	Auto regulator dry weather outlet
NW1-I	Near Lake Avenue and Viking intersection	Auto regulator inlet
NW2-I1	On Desmond Avenue and Lake Road	Auto regulator inlet
NW2-I2	On Lake Avenue and Desmond Road	Auto regulator inlet
NW3-D	North of West Shoreway, in Edgewater Park	Auto regulator dry weather outlet
NW4-D	On Edgewater Drive and West 117th Street intersection	Auto regulator dry weather outlet
NW4-I	On West 117th Street between Lake Avenue and Edgewater Drive	Auto regulator inlet
NW5-D	At West 58th Street, north of Cass Avenue	Auto regulator dry weather outlet
NW5-I	At West 58th Street, north of Cass Avenue	Auto regulator inlet
NW6-D	Rocky River Drive between auto regulator NW6 and Northwest Interceptor	Auto regulator dry weather outlet
NW6-I	Northeast corner of Rocky River Drive and Albers Avenue intersection	Auto regulator inlet
NW7-I	Near West 65th Street and breakwater intersection	Auto regulator inlet
NW8-I	Intersection of West 67th Street and Father Caruso Drive	Auto regulator inlet
NWCA	Westerly Wastewater Treatment Plant	CSOTF Center Channel upstream of gate
NWI-1	Rocky River Drive and Westpark Avenue	Interceptor
NWI-2	1601 West 117th Street	Interceptor
NWI-3	South Marginal Road and Warren Road	Interceptor
NWI-T1	11642 Detroit Avenue	Trunk sewer
PS2	1200 Division Avenue	Pump
PS13	Mary Street at West 4th Street	Pump
PS13-D	Marquardt Avenue at West 7th Street	Pump station discharge line
PS13-O	Overflow conduit from Mary Street Pump Station	Cuyahoga River inflow analysis (water depth only)
QC-1	Westerly Wastewater Treatment Plant	Settled Overflow Channel #1
QC-2	Westerly Wastewater Treatment Plant	Settled Overflow Channel #2
SS-1	4335 Rocky River Drive	Separate sanitary

WESTERLY DISTRICT
PHASE II FACILITIES PLAN

4.0 COLLECTION SYSTEM MODEL DEVELOPMENT

4.1 Model Choice and Description

Phase I study modeling of the Westerly District was performed with Storm Water Management Model (SWMM) for the combined area and contained only the interceptors and some tributary trunk sewers. This study-level modeling was not sufficiently detailed to adequately simulate the dynamic nature of the Westerly Collection System, specifically the automated regulators. For the Phase II study, HydroWorks, a commercially available hydraulic collection system model, was chosen to evaluate the Westerly District. HydroWorks was selected specifically because hydraulic structures operated by Real Time Control (RTC) can be explicitly modeled. This was an important consideration given the plethora of control structures in the Westerly collection system, including the Combined Sewer Overflow Treatment Facility (CSOTF) and 7 automated regulators with Fabridams.

4.2 Model Development Approach

For SSES and modeling projects, data management has been a tedious and difficult task in the past. For the Westerly CSO Facilities Plan, data was managed through the use of ArcView® Geographic Information Systems (GIS) and associated databases. Many sources of data were used to define the sewer system: City of Cleveland sewer maps, orthophotos, entry and non-entry manhole inspections, and other information. All of the data sources were used to inventory, characterize, and hydraulically evaluate (model) the sewer systems tributary to the Westerly Wastewater Treatment Center. A separate document is being prepared and will explain the data management tools developed for the Westerly CSO Facilities Planning Project. However, the following paragraphs provide some brief information.

Data Management

ArcView® holds information in three associated files (*.shp, *.shx, *.dbf). The shape file (*.shp) stores all the graphic information for each individual graphic object (point, line, polygon). The index file (*.shx) holds links between graphics and databases. The database file (*.dbf) holds all the information associated with a graphic object. For instance, a line represents a pipe; thus, the information contained in the database file includes pipe shape, diameter, length, material, slope, invert, etc.

The data for the sewer system modeling resides in four associated files:

-
1. WS1NODE.*** contains manhole information, including ground surface elevations;
 2. WS1LINK.*** contains pipe information, including shape, size, material, and invert elevations;
 3. WS1AREA.*** contains information about the sewer-sheds and their hydrologic characteristics;
 4. WS1CONT.*** contains information about control structures such as weirs, orifices, pump stations, automated regulators, and HydroBrakes; and

ArcView® Tools

Several tools were developed to facilitate the management of the GIS and databases for this project. Specifically, a stand-alone data entry program was written that interacts with the ArcView® data tables and eases the data entry process. This program generates an interactive form that mimics the manhole inspection forms used by the field inspection crews. Hydraulic data, necessary for modeling, also are entered via the form. Thus, all sewer data for the project are held in a family of database tables, linked and fully accessible through the program. This program is called the Sewer Asset Manager (SAM) and was specifically developed for the Westerly CSO project to facilitate data entry. In addition, SAM will be made available to the District for querying and modifying the sewer data in the GIS, once this study is completed.

Besides SAM, other tools were developed to aid the modeling process. These include:

- downstream and upstream tracing tools for checking connectivity;
- area delineation tools for delineating sewer-sheds; and
- a sewer profile drawing tool for validating the sewer data.

Except for the sewer profile drawing tool, all tools will be provided to the District with the closure of this project.

4.3 Definition of Sewer Network for Modeling

Prior to the development of the collection system model, the portion of the system to be modeled was determined. The GIS mapping database developed through the Sewer System Evaluation Survey (SSES) portion of the Westerly District Phase II Facilities Planning Project was used to define the extent of the entire collection system. Then, the sewer network for modeling was defined using the following criteria:

- Combined Sewer Interceptors: Westerly, Walworth Run, Northwest, and Cuyahoga River (Low Level);
- All combined sewer trunk lines downstream of static flow dividers or regulators (regardless of diameter);

-
- Combined sewer trunk lines and tributary lines in special areas of concern (for example, upstream of flooding areas or bottlenecks);
 - Overflow pipes from the flow divider, static regulator, or automated regulator to the discharge point (either a downstream point in the system or the receiving water);
 - Separate sanitary sewers in the over / under areas greater than or equal to 8 inches in diameter, and the storm sewers above these sanitary pipes;
 - Stormwater pipes in the over / under areas that discharge to the receiving water.
 - The Westerly Wastewater Treatment Center and CSOTF.
 - Major stormwater discharge routes to the receiving water from the separate sanitary areas.
 - Any portion of the system needed to insure accurate modeling of the automated regulators and other control structures, particularly if the time of concentration from an area affected regulator operation.

Based on the selection criteria, the sewer network for modeling included all pipes in the separate sanitary areas and pipes 24" in diameter and larger in the combined sewer area.

4.4 Model Simplification

Advances in both computer hardware and software technology have limited the need for simplified models due to long simulation times and disk space limitations. Information is available in the GIS to include every pipe in the sewer network as defined for modeling. However, some model simplifications have virtually no effect on the model results and were made to the Westerly model to reduce its complexity. One such simplification is the elimination of "through" manholes, where the pipe diameter and slope remain the same and no new flows are added to the system. The following criteria were used to determine the necessity of manholes (nodes) in the model network:

- All manholes that receive hydraulic loads from contributing areas;
- All junction manholes at junctions;
- All manholes where pipe shapes change from upstream to downstream;
- All manholes where the pipe sizes change from upstream to downstream;
- All manholes where the pipe gradient changes between the upstream pipe and downstream pipe;
- All manholes where flow monitors were installed;
- All manholes upstream and downstream of flow monitors;
- All manholes receiving hydraulically loaded with industrial flows in the model;
- All manholes containing control structures, such as pumping stations, regulators, tanks, etc.;
- All manholes with steps in invert level between the incoming and outgoing pipes (within 0.2 feet) (ensures that the correct gradients are used in the model and that and hydraulic restrictions are not simplified out of the model).

The Westerly model was simplified to a network containing 2,833 nodes, 2,861 links, 37 outfalls, and 224 controls (including weirs, invert plates, HydroBrakes, automated regulators, and pumping stations). Figure 4-1 shows the simplified sewer network that was modeled. (This large figure can be found folded and placed in the map pocket at the end of this document.)

4.5 Delineation of Sewer Basins and Contributing Area

When developing a collection system model, sewer basins are used to determine the amount of flow that enters the sewer system. These basins are used to determine both the population tributary to the sewer system at various locations and the potential area from which the sewer system receives runoff flows. For the Westerly Collection system model, 1,327 sewer basins were defined to represent flows from the Westerly Service Area.

The primary factor considered for delineating contributing areas was the time of concentration or the amount of time taken for rainfall to hit the ground, runoff, and enter the sewer. If drainage areas are too large, model simulations will not reflect the time of concentration. Generally, the following items are considered when drainage areas are delineated:

- Ground surface contours that affect overland flow;
- Natural boundaries, such as rivers;
- Streets, highways and railroads;
- Property boundaries; and
- The extent of the collection system in the area.

Table 4-1 briefly summarizes the types and numbers of drainage areas delineated for the Westerly District along with a few relevant statistics typically reported for drainage areas. Appendix A contains the full table of drainage areas and the hydrologic parameters determined for each area. The hydrologic parameters are discussed later in this chapter.

In the separate sanitary area, two areas were drawn, one on top of the other (exact replicas), to represent the sanitary flow and rainfall-induced infiltration into the sanitary pipe and the runoff into the storm pipes. The “sanitary” area produces rainfall-induced infiltration / inflow for the sanitary sewer and the “storm” area produces runoff for the storm sewer. This ensured that no more than 100 percent of an area drained into the sewer network. Figure 4-1 also shows the delineated drainage areas for the Westerly Collection System model.

Table 4-1. Drainage Areas for the Westerly Collection System Model

Area Type	No. of Areas	Total Area (Acres)	Population	Area-Weighted Percent Impervious	Area-Weighted Percent Pervious	Total
Combined	648	7,440	126,205	56	40	96
Sanitary	341	1,318	28,643	5	11	100
Storm	338	1,318	-	51	33	
Note: The sanitary and storm areas are duplicated, thus the sum of their percentages equals 100 percent. When the combined areas were delineated, some large areas near the waterfronts were included that drain directly to the watercourses rather than to the combined sewer system. Therefore, less than 100 percent of some of the combined areas is tributary to the collection system.						

4.6 Dry Weather Flow

Dry weather flows in the collection system are comprised of three distinct components: wastewater, infiltration, and river or lake inflow. Wastewater includes sanitary flows generated by population water usage and includes commercial and industrial wastewater. Infiltration results from groundwater entering the collection system through cracks in the pipes, joints, and manholes. The dry weather infiltration also can result from broken water supply mains. River and lake inflow to the collection system occurs when the water level in the river or lake rises above the invert level of an outfall pipe or the crest elevation of a weir.

Wastewater Flows

The wastewater or sanitary component of dry weather flow was determined using population data, per capita wastewater generation rates, and billing records of industrial and commercial sewer customers. In addition to the amount of wastewater generated, the diurnal pattern of flow was determined using flow monitoring data.

Base Flow Development for Residential Land Uses

1990 Census Population data for the Westerly District service area was obtained as a TIGER Line 95 GIS coverage from the United States Department of Commerce Bureau of the Census. This coverage when “intersected” with the sewer basin coverage provides population estimates for each sewer basin by land use classification including residential and commercial / industrial. The model then uses this population estimate, together with a per capita wastewater generation estimate to determine wastewater flows from each sewer basin. The wastewater generation rates used for residential

areas in this study were 115 gallons per capita per day and 150 gallons per capita per day. These two per capita wastewater generation rates reflected different water usage among the residential areas. This topic is discussed in further detail under “Diurnal Flow Pattern Development within this section.

Base Flow Development for Industrial/Commercial Land Uses

Major industrial and commercial flows were determined by inspection of sewer billings. Facilities discharging more than about 23,000 gallons of wastewater per day were included as additional wastewater flow inputs to the model. For these 33 industries, artificial sewer basins with a small (insignificant) population were created to simulate industrial flows.

An artificial population with a high per capita wastewater generation rate was used to represent the industrial flows in each of these artificial sewer basins. These flows are uniformly distributed to simulate weekday working hour periods. A constant industrial per capita wastewater generation rate (23,000 gallons per capita per day) was used to simulate the anticipated total daily flow from the facilities. The anticipated daily flows were obtained from discharge permits. Table 4-2 presents the artificial populations, the model simulated flows, the actual industrial permitted flows, and their input locations.

⁽¹⁾ Industrial flows are generated by an artificial population and per capita flow rate.

Diurnal Flow Pattern Development

Diurnal flow patterns are important because wastewater flows can vary from 60 percent to 130 percent of the average daily wastewater flow depending upon the time of day. The required data to determine the diurnal patterns include a per-capita flow rate and ratios of the flow at specific times of the day versus the average daily flow for both the weekday and weekend. These data were derived from the flow monitoring data collected for this study. As shown in Table 4-3, five diurnal patterns or profiles were used to represent the diurnal wastewater flows. Three of these profiles reflected the different types of housing in the combined and separate areas. The remaining two reflected industrial wastewater generation including industries that operate only on weekdays and those that operate both weekdays and weekends. By defining the diurnal patterns observed in the collection system, the model simulates a more realistic wastewater flow based on the time of day or the day of the week. Figure 4-2 shows the areas defined under each diurnal flow pattern and their corresponding base flow. Figures 4-3 through 4-12 present the weekday and weekend diurnal patterns for the 3 housing and 2 industrial land use types.

Table 4-3. Diurnal Flow Pattern (Profile) Descriptions

Profile	Description
1	Separate area; residential
2	Combined area; residential
3	Combined area; residential
4	Industrial (week day only)
5	Industrial (week days and weekends)

The HydroWorks model uses two files to manage the wastewater flows: the Wastewater Generator file (WWG) and the Land Use Definition file (LUD). The Wastewater Generator file contains the per capita wastewater generation rates and diurnal curves for different land use definitions. The Land Use Definition file contains information about the representative land use types such as the three housing and two industrial types found in the Westerly Service District. Additional information about how HydroWorks uses these two files is found in the Engineer's Guide in the program's help menu.

Infiltration

In HydroWorks, infiltration is simulated as a fixed rate of inflow into the sewer system. Whether from naturally occurring groundwater or saturated earth (from a broken water main, for example), infiltration is determined by comparing predicted dry weather flows with observed flow monitoring data. Essentially, infiltration is calculated as the difference between the observed flow and the flow attributable to population and other wastewater sources, during dry weather flow periods and accounting for diurnal variations. For the Westerly Collection system, infiltration was determined during dry weather flow verification as follows:

- If the dry weather flow simulated by the model was less than observed through the flow monitoring data (and not attributable to flows generated by populations or industries), infiltration flows were added to account for the difference.
- If the dry weather flow simulated by the model was greater than observed through flow monitoring data, the population was redistributed to more accurately reflect the observed dry weather flow. Negative infiltration rates were not used.

Flow monitoring data were used from periods where the flow represented base wastewater and infiltration typical of that time of year. Generally, these periods are found when no rainfall had occurred in the previous 3 days. Thus, the infiltration values represented typical groundwater levels or saturated earth during the flow monitoring period, not delayed rainfall-induced flows.

Through the process of dry weather flow calibration, 10.8 mgd of infiltration was found in the Westerly Collection System. Table 4-4 indicates the location, reference flow monitor, and infiltration flows added to the collection system model.

River and Lake Inflows

For the Westerly District collection system model, river and lake inflows were an important source of flow into the system, particularly along the Cuyahoga River Interceptor. During the SSES portion of this study, field crews observed river and lake water spilling into the system over weirs from submerged outfall pipes. As a result, during an early action project, called the Cuyahoga River Inflow Analysis, it was determined that seven of the Westerly Service Area outfalls were potentially subject to river inflows due to much higher than normal lake levels in 1997. Outfalls with the potential for inflow included 075, 076, 079, 082, 240, 086, and Sycamore Slip (even though collapsed).

River and lake inflows were modeled using river and lake water surface elevations recorded during the flow monitoring period, by specifying depth hydrographs as boundary conditions at the outfalls receiving inflows. The model projected water surface elevations up the outfall pipes. If the water level exceeded the crest of the weir in the overflow chamber, the model calculated a flow rate into the system using standard weir equations. For verification, the actual river / lake levels were used as depth hydrographs. For design and typical year analyses, a standard fixed water surface elevation of 574.5 feet above datum was used. The 574.5 feet is the 95th

percentile water level elevation of Lake Erie, Cuyahoga River, and Rocky River, based on the CRGS datum.

4.7 Wet Weather Flows

Storm flows consist of three major simulated components: dry weather flow (including wastewater, infiltration, and river or lake inflows), runoff from impervious surfaces (including roofs, roads, and pavement), and runoff from pervious areas (such as lawns or other vegetated land areas). Runoff from both impervious and pervious surfaces is simulated using a hydrologic model that calculates the volume of runoff from a rainfall event. Typically, the hydrologic model includes initial losses from depression storage and accounts for time of concentration using the land surface slope and length of flow path.

Hydrologic Model Parameters

For the Westerly Collection System model, the HydroWorks implementation of the SWMM RUNOFF model was used to generate the runoff from pervious and impervious surfaces. SWMM needs the following information to determine the runoff response from rainfall events for the three surface types (Roofs – Type 1; Pavement – Type 2; Grass Areas – Type 3):

- Drainage area
- Percent impervious (types 1 and 2)
- Percent pervious (type 3)
- Effective catchment area width
- Catchment area slope
- Manning's "n" for impervious area (types 1 and 2)
- Manning's "n" for pervious area (type 3)
- Depression storage for impervious area (types 1 and 2)
- Depression storage for pervious area (type 3)
- Initial infiltration rate
- Limiting infiltration rate
- Infiltration rate decay coefficient
- Antecedent conditions

Drainage Area, Width and Slope

The drainage area for each of the sewer-sheds was calculated with the GIS. The method of drainage area (sewer-shed) delineation was discussed in Section 4.5. The width of each drainage area was determined by assuming the area was square; thus, the

catchment width was calculated as the square root of the area and the effective catchment width was twice catchment length. Since the drainage areas were delineated to account for the time of concentration, twice the square root of the catchment area was deemed a reasonable estimate of the effective catchment area width. HydroWorks, unless otherwise specified, determines the catchment slope based on the slopes of the ground surface of pipes receiving flows. Therefore, no estimate of catchment slope was necessary as this adequately represented the local ground slope for pavement (type 2) or grass areas (type 3). For roofs (type 1), a standard slope of 5% was used.

Percent Impervious and Area Types

For the Westerly Collection System model, percent impervious was determined as follows:

1. The Westerly District was examined for typical areas;
2. 5 representative areas were defined;
3. The percent of roof (type 1), pavement (type 2), and grass (type 3) was determined for each representative area;
4. The representative area percentages of roof, pavement and grass were applied to all of the drainage areas.

Table 4-1 shows the area weighted percentages of impervious (types 1 and 2) and pervious (type 3). The table of drainage areas in Appendix A lists the percentages of the three area types (roof, pavement, and grass) for each of the 1,327 sewer-sheds.

Manning's "n" Values

The Manning's "n" values for impervious and pervious areas are used by the model to determine the friction losses from overland flow. The Manning's "n" value for roof and paved impervious areas was 0.04 and was the same value used in the Mill Creek study. For pervious surfaces, a Manning's "n" of 0.3 was used, also the same value used in the Mill Creek study.

Depression Storage

Initial losses or depression storage on impervious surfaces were determined based upon the square root of the slope of each drainage area. HydroWorks uses the following equation to determine initial losses from slope:

For impervious areas: Depression Storage = 0.04 inches / $\sqrt{\text{slope}}$

For pervious areas: Depression Storage = 0.19 inches / $\sqrt{\text{slope}}$

The base values of 0.04 inches and 0.19 inches were those used for impervious and pervious minimum depression storage values, respectively, in the Mill Creek Study.

Infiltration Parameters

After initial losses to depression storage are subtracted, 100 percent of the runoff from impervious surfaces reaches the sewer. For pervious surfaces, however, both initial losses to depression storage and infiltration into the ground determine the final volume of runoff from pervious surfaces. Either the Horton or the Green-Ampt method of calculating infiltration is used to determine runoff losses to infiltration. For the Westerly Collection system model, the Horton infiltration method was used.

The Horton infiltration model governs the amount of runoff from pervious surfaces lost through seepage into the ground and soil through a first-order decay relationship. The Horton infiltration model uses an initial infiltration rate, a limiting infiltration rate and an infiltration decay constant to determine the amount of runoff lost into the soil through infiltration. Similar to the Mill Creek Study area, the Westerly District has type D soils. The Westerly District soils are classified as Urban soils predominantly Mahoning. This soil classification is described as poorly drained silty loam and silty clayey loam. As a D class soil, the initial infiltration rate used for modeling was 5 in/hr and the limiting infiltration rate was 0.25 in/hr. The infiltration decay constant was 2/hr (0.00115/ sec). These values represent published data for type D soils and are consistent with the values used for the Mill Creek model.

Antecedent Conditions

The use of antecedent conditions ensures that the state of soil saturation is accounted for over and above its typical drainage characteristics and is particular for each individual storm. The amount of moisture held within the soil would affect the point at which runoff occurs from pervious surfaces (grassland, etc.). If this occurs early on in a wet weather event, such as when storm follow close to one another, then greater runoff will occur than were a storm to occur after an extended dry period.

Antecedent conditions were determined by evaluating the rainfall during the 24 hours preceding the beginning of a wet weather event. The model accounts for antecedent conditions by applying the antecedent rainfall depth to the ground surface and calculating the available depression storage and infiltration capacity.

4.8 Control Structures

The Westerly Collection System Model has over 200 control structures. These structures include the 7 automated regulators (some with Fabridams), 8 HydroBrakes, 7 pump stations, the CSOTF (CSO Treatment Facility), various weirs, flow dividers, and invert

plates. Although the modeling of these structures in HydroWorks was generally straightforward, a brief description of most is provided in this Section.

HydroBrakes

Eight HydroBrakes are located in the Westerly Collection System on both the Northwest and Westerly interceptors. Their locations are shown on Figure 2-1, and their street locations are listed below:

HB#1:	1497 West 117th Street
HB#2:	West 117th Street north of Berea Road
HB#3:	12920 Berea Road
HB#4:	Lakewood Heights Boulevard east of West 140th Street
HB#5:	West 153rd Street and South Marginal Road
HB#6:	Riverside Drive and Fischer Road
HB#7:	Rocky River Drive and Chatfield Avenue
HB#8:	West 117th Street and Detroit Avenue

These HydroBrakes were detailed in an EPA report “Controlling Discharge and Storage in a Combined Interceptor Sewer - Cleveland, Ohio (HydroBrakes)”, dated July 1987. The report provided information about the locations and discharge characteristics of the HydroBrakes. Each HydroBrake was included in the model as a vortex control device by specifying the stage-discharge curve from this report. These curves are shown in Figures 4-13 through 4-20. The report indicated that a weir was installed at each HydroBrake location to allow overtopping and bypass of the flow control. These weirs also were modeled. In the model, the specified discharge curves have a negative component, which allows for flow reversal through the HydroBrake.

The model simulations were evaluated to ensure that the HydroBrakes were operating correctly by viewing sewer profiles during wet weather events. These profiles show the combined operation of the HydroBrakes to affect storage in the interceptor sewer. The discharge curve for the HydroBrake at West 117th St. and Detroit Avenue was based upon actual and interpretive information contained within the above referenced report.

Pumping Stations

Six pumping stations within the Westerly collection system and one at the CSOTF were included in the model. The six (non-CSOTF) pumping stations in the model are:

- West 61st Street and Barberton Avenue;
- Edgewater Drive and West 112th Street;
- West 3rd Street and Service Court;
- Incinerator and Mahoning Avenue;
- Division Avenue; and
- Mary Street.

Of the non-CSOTF stations, the District operates the Division Avenue Pump Station. The City of Cleveland operates all others.

These six pumping stations were modeled as screw pumps, rather than fixed discharge pumps. Screw pumps were used because their solution algorithm uses smoother calculations, reducing model run times. The operating regime of the actual fixed discharge pumps was reflected in the model.

The individual pumping station operational characteristics were accounted for to ensure that the model simulated the appropriate discharge characteristics. The information used to model these pumping stations was based on prior studies and construction drawings. No pumping station tests were conducted for this study. Figures 4-21 through 4-26 present the pump curves used to represent six of the pumping stations.

The pumping station at the CSOTF was modeled as a fixed discharge pump. The operational characteristics were simulated using real time control rules based upon the known operating strategy of CSOTF. For model simulations, it was assumed that the pump at the CSOTF turns on and empties the tanks at a rate of 14 mgd to the headworks when gravity flows arriving at the headworks fall below 49 mgd.

Regulators and Flow Diversions

Regulators and flow diversions were modeled based upon CSO Phase I survey information that had been verified or updated during this project. Typically, these control structures were fixed weirs or orifices (holes in the base of a pipe where flows drop into another sewer). Instances of pipes leaving manholes at higher elevations were modeled as such rather than as weirs. A few abandoned Brown & Brown mechanical regulators were simulated with appropriately sized pipes and orifice openings.

Auto Regulators

Seven automated regulators were included in the model of the Westerly collection system. The District supplied information about each automated regulator for modeling, including PID coefficients and digital data of their operation. Some flow monitoring data was also collected in the vicinity of the automated regulators. Construction drawings were used to ensure that correct chamber sizes and weir elevations were incorporated into the model.

The District's automated regulators are typically comprised of a gate controlling flow to the WWTP and a Fabridam controlling the overflow. The gates were controlled by Real Time Control (RTC) rules developed for this project, but based on the desired gate operation. The Fabridams were modeled as variable crest weirs and also controlled with RTC rules. The automated regulators included in the model were:

- Lake Ave. and Viking Ave. (NW1);
- Lake Ave. and Desmond Ave. (NW2);
- Edgewater Park (NW3);
- West 117th Street and Edgewater Drive (NW4);
- West 58th Street and Cass (NW5);
- Rocky River Drive and Lorain Avenue (NW6); and
- West 65th Street and Breakwater Dr. (NW7).

Table 4-5 summarizes the real time control rules for CSOTF and each automated regulator. In general, these facilities are controlled using Proportional Integral Differential (PID) logic algorithms that (1) vary gate positions and (2) inflate / deflate bladder-type dams based on flow depths within the interceptor and trunk sewers. Two coefficients govern the PID algorithms: a proportional coefficient and a differential coefficient. The proportional coefficient directly governs the total range in the movement of a gate. For example, a larger proportional coefficient suggests that the gate will have a larger reciprocating range. The differential coefficient governs how much change in gate position can occur within each sensing interval.

Real Time Control Parameters

Table 4-5: Real-Time Control Parameters

Combined Sewer Overflow Treatment Facility (CSOTF)

The CSOTF, a storage and treatment facility for excess wet weather flow, was included in the Westerly collection system model and controlled by RTC rules. Two automated gates control the flows into the storage tanks and flows through the main channel to the Lake. In addition, when flow to the WWTP drops below 49 mgd, the stored sewage is pumped back to the WWTP for treatment before release to Lake Erie. The base flow allowed through the WWTP was limited to 50 mgd based on information supplied. This initial flow rate was increased to 100 mgd under baseline conditions.

Over-Under Sewers (Invert Plates)

The Westerly collection system service area is partially served by separate sanitary sewers. In the separate sanitary area, the storm and sanitary sewers were constructed in a “common trench” with a shared manhole for access at some locations. At manholes shared between the storm and sanitary sewer an invert plate provides access to the sanitary sewer for maintenance (vacuuming or jetting). Figures 4-27 and 4-28 show the invert plates and the configuration of the storm and sanitary sewers at shared manholes.

During the SSES portion of the Phase II study, field crews inspected each manhole in the separate sanitary area to determine the location, size, and condition of the invert plates. A total of 264 invert plate manholes were found in the Westerly District collection system. Their conditions were as follows:

- 55 plates missing
- 46 plates damaged
- 23 plates seated improperly
- 140 plates intact

Since both the storm and sanitary sewers were modeled, the invert plates were represented as an orifice from the sanitary sewer to the storm sewer. The orifice discharge coefficient and opening size were correlated to the condition of the invert plate.

During a rainfall event, flow travels in the storm sewer until an invert plate is encountered. If the invert plate is damaged or dislodged, the flow from the storm sewer enters the sanitary sewers. At some point, the sanitary sewer usually becomes surcharged and flow then travels from the sanitary sewer into the storm sewer through the invert plate openings.

The operational characteristics of the invert plates were fully represented by the orifices used in the model. Specifically, both directions of flow were simulated (from the storm sewer into the sanitary sewer –inflow- and from the sanitary sewer into the storm –

surcharge and contamination). However, the model does not handle the following

FIGURE 4-27

DIAGRAM OF OVER/UNDER SEWER

Figure 4-28. Detail of Invert Plate in Over/Under Sewers

Orthogonal Rendering

Cross-sectional Diagrams

scenario: where sufficient velocity is attained, the flows in the storm sewer could “jump” an invert plate opening. Although, in theory, the invert plate may act as a leaping weir, the only areas affected would be the uppermost portion of the over-under system during the beginning of a storm. Once a storm begins, most of the sanitary sewers in the over-under area become surcharged from inflows through upstream invert plates and “spill” flow back into the storm sewers. This scenario is considered to be a minor model limitation; therefore, this model arrangement was considered satisfactory for simulating invert plates.

5.0 COLLECTION SYSTEM MODEL VERIFICATION

5.1 Verification Events

The model of the Westerly District collection system was verified using two dry weather and three wet weather flow events. The event details are shown in Tables 5-1 and 5-2.

Table 5-1. Dry Weather Flow Verification Events

Date	Duration (hours)	Day
April 26, 1997	24 hours	Saturday (Weekend)
June 11, 1997	24 hours	Wednesday (Weekday)

The flow monitoring data was examined to find days where the flows were at the base flow rate without rainfall derived infiltration / inflow. The above dry weather flow days were chosen because no rainfall occurred during the two previous days and the flows were approximately equal to the expected base flow.

Table 5-2. Wet Weather Flow Verification Events

Date	Duration Ranges (hrs:min)	Rainfall Depths (inches)							Antecedent Depth (inches)	Peak Intensity (in/hr)
		RG 1	RG 2	RG 3	RG 4	RG 5	RG 6	RG 7		
April 12	13:50 - 15:20	0.96	0.96	0.96	1.12	1.12	1.2	1.1	0.0	0.36 – 0.60
May 31	35:00 - 35:55	2.12	2.36	2.68	2.22	2.90	2.71	2.71	0.2	0.48 – 0.96
June 2	4:30 - 5:55	0.89	1.16	0.78	0.84	1.29	1.06	1.06	1.4	0.48 – 1.32

From the 44 rainfall events (see Table 3-1) recorded during the flow monitoring period, only 17 storms had recorded depths greater than 0.2 inches with all rainfall gauges operational. Of these 17 storms, only 7 events had recorded rainfall depths greater than 0.5 inches. However, for one of the seven storms, many of the flow monitors had been removed; therefore, only 6 of the 44 storms were chosen as potential verification wet

weather events. Of the 6 events, the three largest volume storms averaged among the 7 rain gauges were chosen as the verification storms.

5.2 Dry Weather Flow

For the two dry weather events, the model predicted flows were compared with the observed flows to determine:

- Modeling anomalies;
- Flow data discrepancies; and
- Manhole or pipe data errors.

The initial modeling results compared well with the observed flow data. Where the model results did not compare well with the observed dry weather flow monitoring data, the connectivity of the model network was re-evaluated. Once connectivity discrepancies were resolved, the distribution of population was re-examined and redistributed as appropriate based on building locations and other information. After the population distribution was investigated, areas deficient in flow were investigated for large sources of trade flow (large sewer users). Several additional industrial flows were added to the model to improve the verification. These flows are listed in Table 4-2. If population distribution or larger trade flow sources did not explain the discrepancies between observed and modeled flows, infiltration flows were allocated throughout the collection system to account for the additional base flow. About 10.8 mgd of infiltration was added throughout the collection system to make up the base flow. Appendices B and C present the hydrographs comparing observed and simulated dry weather flows.

The model was considered calibrated for dry weather flow.

5.3 Wet Weather

After the model was calibrated for dry weather flows, the verification rainfall events were modeled and the results compared with the flow monitoring data. Typically, flows were compared unless the monitoring data was questionable; then, the depths were compared. The objective of the comparison was to ensure that the model adequately represents the runoff response from rainfall events.

The verification process involved identifying discrepancies between observed and simulated flows, investigating the discrepancies, and correcting model parameters. Typical problems evaluated during verification included:

- Under- or over-predicting runoff volumes;
- Inaccurate representation of pump station operation;
- Over-predicting flooding
- Over-predicting surcharging

-
- Spatial rainfall
 - Hydrograph runoff decay
 - Under estimating in-system storage

Before investigating discrepancies, the flow monitoring data was evaluated for reasonableness. Some factors that were considered in evaluating the flow monitoring data included:

- whether depth and velocity sensors were operational (with reference to flow, depth, velocity, and scatter graphs);
- whether the sensors recorded similar responses for similar storms;
- if either sensor was blocked by debris;
- if site hydraulic conditions were likely to produce valid data; and,
- if other flow monitors in the vicinity confirm the data (mass balance).

If the velocity data was questionable, but the depth data seemed reasonable, the model was verified with depth data. In the absence of good or reasonable data, the model was not verified with flow monitoring data in that location.

Along with an evaluation of the flow monitoring data, wet weather connectivity (stormwater outlets) and sewer maintenance data were used to evaluate the comparison of simulated and observed flows. For instance, if blockages were suspected, flow monitor inspection logs and sewer maintenance logs were consulted to confirm a blockage existed. Since blockages are temporary they are generally not modeled unless the model could not be verified for other wet weather event simulations. This circumstance did not occur during the Westerly project. All instances where flow monitoring data may have suggested a blockage during a particular storm were verified during other wet weather events.

If evaluation of the flow monitoring data, connectivity, and operational logs, did not resolve the verification, the contributing drainage area percentage impervious allocations were inspected for gross errors (mistakes). Where reasonable, adjustments were made to percent impervious allocations in areas of poor model verification. However, unrealistic changes were not considered or implemented.

Verification proceeds from the upstream areas to the downstream areas. Since the majority of the pump stations, HydroBrakes, and automated regulators were located “downstream” in the system, the operation of these controls was investigated towards the end of verification. To start verification, these structures were simulated as their operational plans indicated. However, as verification proceeded, some minor changes to the original operational rules were made to improve the comparison of modeled and observed flows. For instance, one CSO was known to have a blockage of consolidated

sediment. For verification, sediment was added into the model to simulate this blockage. Typically, the hydraulics around the control structures produced unfavorable conditions for recording good flow monitoring data. Therefore, the verification of these structures focused on simulating their operational plan behavior, not necessarily mimicking the flow monitoring data. As an example, Figure 5-1 presents the sewer

profile through the HydroBrakes, illustrating their operational behavior of creating storage in the Northwest and Westerly Interceptors.

Model verification is evaluated by comparing the observed and predicted flows during dry and wet weather flow conditions. For the events during the monitoring period, the predicted flows compared to the observed flows should meet the following criteria:

- 1) peak flow rate is within +30% and -20%;
- 2) volume of flow is within +30% and -20%;
- 3) general shape of both hydrographs is similar; and
- 4) the above criteria should be met for 2 of 3 storms, unless circumstances at the monitoring locations a) cannot be modeled and are determined to be unimportant, b) are not detrimental to the model, or c) are due to infiltration and can be accounted for in subsequent use of the model.

These criteria are similar to that presented in WaPUG's¹ *Code of Practice for the Hydraulic Modeling of Sewer Systems*, November 1993. Currently, USEPA's *Combined Sewer Overflows: Guidance for Monitoring and Modeling*, dated December 1996, is issued in draft form and provides only vague non-numerical criteria for calibration assessment.

Of the 106 flow monitors, 97 were located in the collection system and used for flow verification. The comparison plots of the model-predicted peak flows, peak depths and volumes relative to corresponding observed values, for the wet weather events of April 12, 1997, May 31, 1997 and June 2, 1997, are located in Appendices D, E, and F, respectively. Appendix G summarizes the verification status of the model for each flow monitor for each wet weather event. Further, it provides an overall model verification conclusion for each flow monitor.

Appendix H further details the information presented in Appendix G by presenting (1) the percent differences between model-predicted peak flows and volumes relative to corresponding observed values and (2) the differences in predicted peak flow depths versus observed flow depths. There are 95 meters that provided flow data in the collection system during the April 12 and May 31 storm events. For the June 2 storm, 91 meters successfully provided flow data. This provides a total of 281 meter-events for evaluation. Figure 5-2 presents of a summary of the percent differences between predicted peak flows and corresponding observed values for the three calibration storms. With respect to peak flow percent differences, most of the values are in the –

¹ WaPUG stands for Wallingford Procedure Users Group, an organization of model users in the United Kingdom. The group meets regularly to discuss modeling, including flow monitoring, model building and testing, calibration and verification, and documentation.

20% to +30% range, and thereby achieve the desired accuracy. The larger differences

Figure 5-2. Peak Flow Comparison - All 3 Events

that exist, however, are typically associated with meter installations on smaller pipes that drain relatively small catchments where flows are highly variable, inconsistent and ultimately difficult to calibrate models. These catchments contribute little to the overall wet weather response in the collection system. Furthermore, other general collection system issues made calibration activities more challenging at some meter installations for some wet weather events. These include:

- Poor flow data (ragging, turbulence, flows too low to be recorded by probes, etc.);
- Operation and maintenance problems, such as blockages;
- Simplified representation of system in peripheral sewer-sheds;
- Over-prediction of flooding and spills in peripheral areas;
- Unknown connections between sewer branches or storm and sanitary sewers;
- Complex interaction between sewers in over / under sewer systems; and
- Complex nature of hydrological processes (non-linear rainfall-runoff relationship).

As a result of these issues, segments of the model are not well verified against some flow meters during some wet weather events. This can be expected in a sewer system as hydraulically complicated as the Westerly District Collection System. Structures with such complex hydraulics during storm flows, such as the automated regulators and invert plates mingling storm and sanitary flows, present difficult site conditions for the collection of valuable flow data. The collected data has been examined in detail and every effort has been made to use this information when possible. In addition to the three verification storms, other collected data was consulted to develop understanding of site characteristics and hydraulic behaviors.

Overall, the model was considered reasonably verified in its prediction of wet weather flows in the system along with the operation of the control structures, particularly the HydroBrakes, automated regulators, and CSOTF. In addition, the extremely complex flow regimes in the separate sewer area with its abundance of invert plates have been calibrated. The District now has a powerful tool with which to evaluate the Westerly Collection System.

5.4 Verification Results

The model was reasonably verified with 2 dry weather and 3 wet weather events. The wet weather events used for verification were the largest storms that occurred during the flow monitoring period. Many of the discrepancies between the model results and the observed data were explained through the investigation of the site hydraulics. In some cases, monitors were installed at locations where the site hydraulics precluded the

collection of good data. In addition, some blockages occurred in the system that prevented the collection of good data. The model was not altered to reflect these blockages if they were documented and explainable.

12" clay sand

4-20-11

57

Site sketch (show flow direction, probe placement and manhole location)

Site Location:

A hand-drawn map of the Clifton area. The word "CLIFTON" is written in the upper center. To the left, "SCHOOL" is written above "FLAG POLE". Below "FLAG POLE" is a small circle with an arrow pointing to the right. In the center, "LAKE ISLAND" is written vertically. To the right of "LAKE ISLAND" is a circle with an 'X' inside. The map is drawn with simple black lines on a white background.
